"- The stress is not a non-specific reaction: The **pattern** of the stress reaction... affects certain **organs** in a highly selective manner.

"- Stress is not necessarily something bad... The stress of exhilarating, creative, successful work is beneficial, while that of failure, humiliation, infection is detrimental.

"- Stress cannot and should not be avoided" (Ibid, p.63)

The concept of stress is closely related to the **General adaptation syndrome** concept, also introduced by SELYE.

While it is originally biological, it could quite probably be usefully generalized to psychology (HORVATH, 1959), to the social sciences (M. Mc LUHAN) and to any type of systems in general.

According to M. TIMSIT-BERTHIER (see Ph. LAMBERT, 1998), the mental component of stress - which probably never appears in animals, because their **behavior** is mainly organized at the limbic **level** of their **brain** - becomes very important and probably dominant in the human species.

"Stress traduces any **semantic** or psychological **reaction** of an individual who feels that what is demanded from him exceeds his/her possibilities of **response**" (p.331)

It is of course difficult in most cases to differentiate both aspects: "Is the marathon runner becoming physically stressed when the **rhythm** of the race becomes unsustainable for him, or mentally when he is not anymore able to maintain himself on par with his competitors?"

In practical contemporary life, negative future expectations - whether imaginary or more or less founded (fear of losing one's job for ex.) - which are mental and psychological, seem to make psychological stress as the initial stage of the **process**, which becomes basically psychosomatic.

This seems closely connected with the development of **time perception** in man. "It is now known that it is not so much the intensity of the hormonal secretions than their disorganization in the temporal dimension that leads to pathological **effects**" (p.339)

G. BATESON made the curious comment that "... stress is a lack of **entropy**, a condition arising when the external **environment** or internal sickness makes excessive or contradictory demands on an **organism's** ability to adjust (1979, p.230).

Would this not be better expressed as "a lack of capacity to produce **entropy**". BATESON himself adds indeed: "The organism lacks and needs **flexibility** having used up its available commitments alternatives" (Ibid).

3221

STRESSOR ²⁾

"That which produces stress" (H. SELYE, 1975, p.78).

Or, according to O.R. YOUNG: "... any externally or internally generated force or **process** which threatens a system's **stability** in one or more respects" (1964, p.80).

Stressors may be external or internal, momentaneous or permanent. They are sometimes easily identified, but in some other cases they can be quite hidden.

3222

STRUCTURAL ANALYSIS ²⁾

R. ROSEN states: "The entire **process**... beginning with the isolation of atomic **subsystems**, their recombination to generate a large class of systems, and the **rules** for selection a subclass of system of interest out of these, are implicit in the notion of '**structuralism**' or structural analysis for the study of **complex systems**. We have amply seen that the word '**structure**' has to be interpreted in a very wide sense; indeed in biology the relevant '**structures**' are always defined in functional terms" (1972, p. 63).

This is not only true in biology: any **functional process** that can be observed corresponds to a **structure** and, furthermore many observed **structures** are only the visible appearance of a **long or very long term** ongoing **process**.

3223

STRUCTURAL CLASS ²⁾

"A set of two or more **objects** (X) or **environments** (X-) that have one or more structural properties in common" (R.L. ACKOFF & F.E. EMERY, 1972, p.18).

ACKOFF and EMERY state: "Thus **structure** is a general concept applicable to geometric, kinematic and mechanical properties, and to any properties that can be expressed as **functions** of them" (Ibid).

In other words it is a powerful source of **isomorphies**.

3224

STRUCTURAL COUPLING ²⁾ - 5)

Reciprocal structural modifications in two **autopoietic systems**, whose **interactions** are **recursive** or very **stable** and which disturb each other (W. KARGL, 1991, p.585).

This concept corresponds to systemic **familial therapy**, but could have applications in the case of economic or **social systems**, and even possibly in physics (binary stars systems).

→ **Coupling (Structural)**

3225

STRUCTURAL DIFFERENTIAL ²⁾

A diagram that can be used to clarify the **semantic** aspects of an **observer's relations** with "reality".

The Structural Differential was introduced in 1933 by the Polish-American linguist and psychologist A. KORZYBSKI (1950a, p.387). His point was to induce a clear **perception** of the differences between outside reality, **perception**, **description** and labelling. He writes (observe his use of quote marks, which mean in every case "that something that we call..."):

"If we take something, let us say the **object**... called "pencil", and enquire what it represents, according to science 1933, we find that the "scientific **object**" represents an "**event**", a mad dance of "electrons", which is different every instant, which never repeats itself, which is known to consist of extremely complex **dynamic processes** of very fine **structure**, acted upon by, and reacting upon, the rest of the universe, inextricably connected with everything else and dependent on everything else. If we inquire *how many characteristics*... we should ascribe to such an **event**, the only possible answer is that we should ascribe to an **event** infinite numbers of characteristics, as it represents a **process** which never stops in one form or another; neither, to the best of our **knowledge**, does it repeat itself.

"In our diagram... we indicate this by a parabola A, which is supposed to extend indefinitely, which extension we indicate by a broken off line B. We symbolize the characteristics by small circles C, the number of which is obviously indefinitely great.

"Underneath, we symbolize the **"object"** by the circle O, which has a finite size. The characteristics of the **object** we also denote by similar little circles C'. The number of characteristics which an **object** has is large, but *finite*, and is denoted by the finite number of the small circles C'.

"Then we attach a **label** to the **object**, its name, let us say "pencil", which we indicate in our diagram by the **label** L. We ascribe also characteristics to the **label** and we indicate these characteristics by the little circles C'.

"The number of characteristics which we ascribe by *definition* to the **label** is still smaller than the number of characteristics the **object** has. To the label "pencil" we would ascribe, perhaps its length, tickness, shape, colour, hardness. But we would mostly *disregard* the accidental characteristics, such as a scratch on its surface, or the kind of glue by which the two wooden parts of the objective "pencil" are held together. If we want an objective "pencil" and come to a shop to purchase one, we say so and specify verbally only these characteristics

which are of particular *immediate interest* to us...

"If we inquire as to the neurological **processes** involved in registering the **object**, we find that the nervous system has *abstracted*, from the infinite numbers of sub-microscopic characteristics of the **event**, a large but finite number of macroscopic characteristics...

"But this is not all. The **object** represents in this **language** a gross macroscopic **abstraction**, for our nervous system is not adapted for abstracting directly the infinite number of characteristics which the endlessly complex dynamic **structure** of the **event** represents. We must consider the **object** as a *first abstraction* (with a finite number of characteristics).

...
"The **label**, the *importance* of which lies in its *meanings* to us, represents a still higher **abstraction** from the **event**, and usually **labels**, also, a **semantic reaction**" (1950, p.387-9).

It is impossible to do justice to KORZYBSKI fundamental work through a short quotation.

He also uses the structural differential to clarify the **relations** between different **labels** of the same **"object"** and the successively more abstract **labels** that can be attached for different **purposes**, to an **event** as for example: "Max", "German shepherd", "dog", "mammal", "vertebrate", "animal", "living being", "life".

The content of his work constitutes a complete course in mental sanitation and he must be considered one of the most important pioneers of Systemics.

3226

STRUCTURAL MODELING

→ Interpretive structural modeling

3227

STRUCTURAL SATURATION ²⁾⁴⁾

The critical **threshold** beyond which more structure building becomes redundant.

Such **thresholds** seem to result from **interactions mechanisms**, either automatic as for example in termites building their nest under the influence of emitted and perceived **pheromones**, or through the direct **perception** of some **redundancy level**, as in human social **behavior**. (Overburdening bureaucracy for instance)

M. MARUYAMA, in an off-hand comment, once observed that two post-offices are never built close to each other, because such a **redundancy** would be very inefficient.

3228

STRUCTURALISM ^{1) - 3) - 4)}

R.M. SNOW considers structuralism "as the continental variant of systems thinking" (1993, p.138).

This seems a somewhat excessive view. Systems thinking has many roots, even in Europe. The **Gestalt** movement (KOHLER, KOFFKA), for instance, is no less important than linguistic structuralism (SAUSSURE, JAKOBSON) or psychological or anthropological structuralism (PIAGET, LEVI-STRAUSS).

It is however true that: "Structuralists emphasize the systems **elements** and their **interrelationships**, and how these are transformed in surface/conscious structure. Structure and any **change** therein are considered sufficient means for exploring both individual and collective **behavior**. The question of **function** or **purpose** is rarely addressed. When it is considered, systemic **action** toward a **goal** is viewed as constrained or determined by the structure which produces it" (Ibid., p.139).

This statement makes clear that structuralism does not merely implies a **synchronic** viewpoint, but altogether a **diachronic** one.

This point is however not obvious for everybody (not even for some structuralists themselves). As noted by H. SABELLI: "**Structure** is opposed to **change** and appearances..."

Figure: see entry STRUCTURAL DIFFERENTIAL

KORZYBSKI's Structural differential used for modelling the Abstraction process
Ch. FRANÇOIS

"This implies a danger to dismiss what is evident as mere **emergence**, overvaluing speculations and rationalizations. Structuralism leads us to overvalue **similarities** at the cost of **differences** and **stability** at the cost of **change**" (pers. comm., 1994).

M.C. JACKSON retains a practical orientation in structuralism, which: "... in the realist form, is concerned with uncovering and **understanding** the underlying **structures** or systems of **relationships** that generate the surface **phenomena** perceived in the world. It demands explanation of the **phenomena** available to our senses in terms of the underlying, unobservable **mechanisms** that generate them. Structuralists attempt to provide **models** of the causal **processes** at work at the deep structural level..." (1992, p.23).

"A movement in social science, originated by Cl. LEVI-STRAUSS, which supposes that social **structures** depend on certain basic characteristics of human **brain programs**, giving specially attention to **binary** operations that are used in **communication**" (J.Z. YOUNG, 1978, p.299).

YOUNG adds: "Structuralism" is also sometimes used to define the type of **linguistics** that studies surface structures rather than CHOMSKY's more abstract deep structure" (Ibid.)

3229

STRUCTURALISM and HISTORICISM¹⁾ - 3)

BLAUBERG, SADOVSKY and YUDIN point out: "In the literature on the question, structuralism is not infrequently presented as antithetic to historicism. It is stated that any structural research rejects the historical approach in principle" (1977, p.31). The authors do not accept this viewpoint.

This observation is concurrent to others by different authors and corresponds to a tendency to formalism noted in the works of some structuralists (in linguistics and cultural anthropology for example).

On the other hand an a-historical stand is only part of a non-dynamical one and serves as a basis for an artificial opposition between structure and function.

Obviously, however structure is a historic remainder or **memory** of a probably more or less **cyclic process** and it can persist on a **long term** basis in the future only if the **process** remains functional.

Furthermore, **behavior** is incited by **structures**, which are traces of older **behavior** (cf. the concept of **stigmergy**).

3230

STRUCTURE¹⁾ - 2)

The **set** of the stable **interrelations** between the **elements** or **components** of an entity (or system).

M. BUNGE extends structure to the **relations** among the **components** of the system and the **environment** (1979, p.4).

Many different definitions have been enounced by numerous authors, as for example:

"The arrangement of the **subsystems** and **components** in three-dimensional **space** at a given moment of **time**" (J. MILLER, 1978, p.22).

The Argentinian biologist M. CEREJIDO proposes a very similar definition, but makes the following comment: "The instantaneous disposition is frequently called **configuration**", while "structure" would be the durable disposition, i.e. what successive dispositions have in common" (1978, p.29).

According to FEIBLEMAN & FRIEND "Structure is the sharing of **subparts** between **parts**" (1945 - 1969, p.48).

They complete this definition in the following significant way: "In every **action**, there is a sharing and an **interchange**".

Thereafter they comment: "The sharing which constitutes the structure is from the point of view of the **whole** represented by the sharing which constitutes the **function**".

This was formulated in a striking way by E. JANTSCH, in terms of "Spatial self-balancing of a system of **processes**. Their **interaction** generates structures which may be compared to standing-wave **patterns** rather than solid constructs" (1975, p.27). See for example: "**Soliton**".

In the same vein, K. KRIPPENDORFF states: "Any **communication process**, once initiated and maintained, leads to the genesis of social structure, whether or not such structure is anticipated or deemed desirable" (1971, p.171). This is a very interesting insight in relation to various systemic concepts: **morphogenesis**, **sybiosis**, **parasitism**...

G. KLAUS definition is still less static: "Set of the material relations existing between active **elements** in a dynamical system" (1976, p.79).

In other words, it is impossible to leave aside the concept of **time**, even in such an apparently static notion as structure. In BLAUBERG, SADOVSKY and YUDIN's words: "The point is that a complete **abstraction** from any time is only possible in a strictly limited class of problems dealing with the investigation of the anatomy or the **morphology** of the **object**, when analysis of its *purely synchronic* cross-section becomes both possible and necessary.

"Knowing the composition of the **object**, its anatomy and **morphology** does not imply however, **knowledge** of its **structure**. Structure is not dead cast of the **frozen object**, but a characteristic of those of its invariant aspects which are only revealed during the analysis of its actual **dynamics**" (1977, p.236).

A good example is petrified wood, in which the relative **relations** among **parts** have been conserved, while the *nature* of the **parts** themselves has changed: complex chemical reactions have replaced wood by stone, in the course of eons.

However, while being not only **synchronic**, but altogether **diachronic**, structures are repetitive in a **cyclic**, **hypercyclic** or **cyclomorphic** way, within the **autopoietic** frame of **organizational closure**.

This point is clearly made by W.R. ASHBY, who writes: "... the structure of **"machines"** appears when the **laws** that govern the system are invariant in **time**" (1964, p.93). Or, in other words: no structures without permanent **constraints**.

Differently, **evolution** signals itself by innovative **events**.

In R. FIVAZ the global structure of a system is: "described by one or several **order parameters**" (1991, p.32).

This connects the concept of structure with **synergetics**.

Structures can be represented by **graphs**, some types more easily than others, as for example **linear** chained structures, circular, or **cyclical** structures, or centered structures, described by B. WALLISER (1977, p.52). When oriented, **graphs** give some idea of the **dynamics** of the structure, as for example in the basic **schemas** of **systems dynamics**. As observed by J.van GIGCH, structures are frequently **hierarchic** (1978, p.15). However, in **networks** for example, this is not necessarily so.

3231

STRUCTURE and EVOLUTION¹⁾

Structure, under its **diachronic** guise, is the **repertory** of those **transformations** acceptable for the system (i.e. corresponding to its **variety** content in ASHBY's sense).

Strictly speaking it would be better to say that systems do not *evolve*, but undergo **transformations** (allowed by their structure).

However, when "the alteration is so important as to become necessarily irreversible, an historical **process** takes place, giving birth to a new structure" (J.L.LE MOIGNE, after J.G. MILLER).

C. BRESCH in his comprehensive study of evolution (1977) observed that structure tends to be structuring, i.e. to generate **complementary** or countervailing structures.

He also explained that structures develop out of **components**, but within the **limits** of pre-existing **constraints**.

→ **Auto-genetic systems precursors; Co-evolution; Structure (Conservative); Structure genesis (Law of); Zero-system**

3232

STRUCTURE and PROCESS^{1) - 2)}

Structure and process (and also **function**) are intimately related. E. JANTSCH writes: "In a **nonequilibrium** world of self-realizing, self-balancing systems, process and structure become complementary aspects of the same overall order of process, or *evolution*. As interacting process define temporary structures – comparable to standing-wave **patterns** in physics – so structures define new processes, which in turn give rise to new temporary structures. Where process carries the momentum of **energy** **unfoldment**, structure permits the focusing and acting out of **energy**" (1976, p.39).

See for ex.: "**Soliton**".

Generally, **evolution** seems to be a result of **dissipative structuration** in far-from-equilibrium systems, which allows for upgrading of **organization** through an increased **energy** consumption and **entropy** production.

3233

STRUCTURE (Conservative)²⁾

A structure which is constantly reproduced.

Conservative structures are a basic feature of **autopoiesis**. They are transmitted through **self-referential processes** and specific **channels** such as DNA, **neural nets**, or cultural **values**.

The process of **reproduction** of conservative structures is akin to the **stigmergy process**.

3234

STRUCTURE (Deep)²⁾

Some systems are able to resist complete dissolution when submitted to violent **turbulence** and may restructure themselves at a higher level of **complexity**. In such cases, they do not lose completely their former structure, of which the subsisting part has been called "deep structure" by E. JANTSCH.

Ch. SMITH resumes as follows this concept: "This deep structure, as explained by JANTSCH, might be locked at as the evolutionary **state** of the system, the degree of sophistication or elaboration that the system has attained and that is irreversible even in the face of forces of dissolution. The deep structure thus serves as a **self-referencing framework** for experimenting **behavior**, pruning **choices** and guiding movement toward new structures. The structures adopted will be consonant with the system's accumulated evolutionary **learning**, its previously developed capacity to maintain **viability** amidst the **complexity** of its **environment**" (1986, p.206).

Somehow a really deep evolutionary **transformation** of the system implies the destruction of the superstructures, but not of the basic core of **organization** in its most general features.

The concept of deep structure seems relevant for example, to chrysalides, at biological **level** and probably to basic mutations as in GOULD and ELDREDGE's punctuated **evolution**. Important cultural mutations possibly follow the same **pattern**: e.g. the **survival** of Greek and Roman cultural structures in Christian cultures.

→ **Radiation (Self-contained)**

3235

STRUCTURE (Dissipative)^{1) - 2) - 4)}

"... the ordered **configuration** that emerge beyond **instability** of the **thermodynamic** branch".

This G. NICOLIS and I. PRIGOGINE (1978, p.60) definition comes as a conclusion to their introductory chapter on **nonlinear thermodynamics**.

I. PRIGOGINE described dissipative structures as "... in **far- from- equilibrium** conditions, **states of matter** characterized by coherent **space-time behavior**" (1973, p.565). He also wrote: "... dissipative structures... are formed and maintained through the exchange of **energy** and **matter** in **non-equilibrium** conditions". He associates this with "creation of **order**" (p.581). However, in the very **process** of dissipative structuration, a **stochastic event** normally acts as a **trigger** (1976, p.93).

PRIGOGINE makes another very significant statement: "... the dimensions of the system play an essential role in the formation of dissipative structures. A sufficiently small system will always be dominated by the **boundary conditions** (NAZAREA, 1974). In order for the **nonlinearities** to be able to lead to a **choice** between various solutions, it is necessary to go beyond some **critical spatial dimensions** (HANSON, 1974). It is only then that the system acquires some **autonomy** with respect to the outside world" (p.101).

E.J. KROWITZ explicits the **concept** in the following way (after BAHG Chang Gen, 1990): "Three conditions identify a dissipative structure:

- The system is **open** with continual interchange with its **environment**;
- The system is in a **state** of damped **instability**;
- The evolutionary **path** of the system stems from **fluctuations** which push the dynamic structure from one **state** to another" (1991, p.47).

Dissipative structures were first observed in the opening years of 20th. Century by the French physicist H. BÉNARD, who observed the progressive **emergence** of **hexagonal** convective cells, replacing simple thermal agitation, in a heated liquid, once a critical temperature **gradient** is reached, i.e. when **thermodynamic equilibrium** is breached.

This corresponds to **symmetry breaking** resulting from a considerable **input of energy**.

Analogous **phenomena** were observed by PRIGOGINE and his groups in a wide variety of physical, chemical, biological, and even later in **social systems**, which receive increasing **inputs of energy** and, as a result, start to develop evergrowing **fluctuations** and react by creating organized (or more organized) **macro-structures**.

Starting from these observations, PRIGOGINE created his generalized **thermodynamics**, applied to all **systems far away from equilibrium**

"The **stability** of dissipative structures is different in kind of **stability** in **steady states**. It is not a result of a low **production of entropy**, but instead, of their ability to transfer to their **environment** great quantities of **entropy**, due to their greater **complexity** (for example under the guise of heat or degraded products). Consequently, when a system organized through dissipative structures does appear, its **environment** tends to become growingly disorganized...

"Dissipative structures result of great imbalances and *maintain themselves* as long as these imbalances subsist. **Processes** which reduce **gradients**, as for example **diffusion**, destroy these structures" (1992).

E. JANTSCH states: "The concept of dissipative structure also implies that the **environment** is necessary to maintain the dissipative structure; unlike **equilibrium structures**, dissipative structures cannot exist independently" (1976, p.40)

It is however very questionable if **equilibrium structures** could do without **environment**. Are they not stabilized former dissipative structures, i.e. having secured the needed permanent **energy inputs**... and even the result of a former stage of **metastability**?

As a result, a system whose **organization** has been upgraded through structuration by dissipation of supplementary **energy**, cannot anymore survive without this supplement.

Through dissipative structures a system is not merely able to absorb more **energy** and **matter**: it reacts to these excess **inputs** and becomes able to use them by reorganizing itself in its own ways. This may be considered as a generalization of the biological concepts of **anabolism**, **metabolism** and **catabolism**, in **morphogenesis** conditions.

The newly emerging structure finally finds its own permanence **limits**, according to the steadiness of the supplementary **inputs** it receives.

PRIGOGINE also states: "A system may undergo various successive **processes** of structuration through crisis. A **bifurcation** of its **evolution** characterizes each of these **processes**" (1992).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The dissipative structure concept seems to be of utmost importance for the study of the man-planet system presently in course of shaping, specially in relation to:

- the **growth** and acceleration of **flows** through human **organizations**
- the very speedy shaping of new and ever-more complex social structures
- the growing disruption of the global **environment**.

3236

STRUCTURE (Fractal)²⁾

A ramified or subdivided structure, **self-similar** at different **levels**.

Discovered as a mathematical structure by B. MANDELBROT, it is now used to modelize a great number of **self-similar concrete systems** or structures, as for example geographic features as coastlines, or river **basins**; networks ofismic faults; roots and branches of trees; bronchial and lungs structures. H. SABELLI observes that fractal structures, in biological systems, allows for the formation of complex and even irregular structures, starting from a quite simple genetic **template**.

Fractalization in structures also permits an optimum use of available **space**, through miniaturization or micronization.

3237

STRUCTURE (Hierarchic)²⁾

A **multi-level** structure, where some **components, parts** or **subsystems** are subordinated to other ones.

Hierarchic structures appear in **complex systems** with **regulations**. Normally a regulator *manages* or *controls* some functional-structural **subsystem**, or the **relationship** between two or more **subsystems**.

In many cases, different local or specific **regulators** must be controlled or coordinated and a supra-**regulator** becomes necessary. Hierarchic structures thus build up in a progressive way.

Like any structure, they are **diachronic** as well as **synchronic**. Some of them do only become visible in the **time** dimension, due to the widely different **periods** of many **regulations**, and cannot, for this reason, be observed statically.

This is specially of utmost importance for the understanding and management of **human systems**, wherein **long-term** structural effects are many times ignored.

E. JANTSCH states: "Hierarchical **description** of structure usually express the ideal of **equilibrium** both at a given structural **level** and in the relations between **levels**" (1976, p.51).

Hierarchic structures are characteristic of strongly integrated systems, tending to **homeostasis**. Such systems are prone to growing **rigidity** with time.

3238

STRUCTURE (Lacunar)²⁾

In relation to CANTOR's triadic set, M. DUBOIS, P. ATTEEN and P. BERGE explain as follows the nature of fractal dimensions:

"The set thus obtained is formed by rigorously ordered points, even if they seem irregularly distributed. Like all **fractal objects**, this **set** possesses a lacunar structure, which may be expressed by saying that its dimension is not whole, that it is "**fractal**". It is in no way a curve in view that an infinity of segments are not included. Its dimension is contained between 0 and 1 (0.63...) The same type of structure, in a qualitative sense, is to be found in a transversal section (i.e. a **POINCARÉ section** of the **chaotic attractor** constructed by contraction, stretching and folding ad infinitum of a small rectangle in the **phases space**. These **operations** transform a segment inside of the rectangle in the **phases space** into a **set** of points... whose dimension is also less than 1... As to the **attractor** it spreads out... in a complex fashion in a three-dimensional space. Its dimension is contained between 2 and 3." (1987, p.197).

3239

STRUCTURE (Reference)

→ **Stigmergy**

3240

STRUCTURE (Self-facilitating)^{1) - 2) - 3)}

This concept proposed by R.W. FULLER and P. PUTNAM, is interesting because it connects structure and **function**.

The authors explain that, in **networks**, structures tend to be self-reinforcing through the following **mechanism**: **random search processes** in the **network** tend to produce the **emergence** of **relative dominance** of some **patterns** (crf. D. HEBB's **habituation**). This in turn tends to stop the **random search**:

"What stops a **random search** is reinforced again and again – every time the associated **drive factor** is excited – because what satisfies a **drive factor** once will do so again if it catches the basic principle involved" (1967, p.105).

... and: "The historical sequence of **random searches** becomes linked together in a chain" (Ibid., p. 106)

3241

STRUCTURE from ORDER^{1) - 3)}

D. BOHM and F.D. PEAT write: "The concept of **order** is, by itself, of very general interest. But one of its most fundamental and deepest **meaning** is that it lies at the root of structure, which is a key **issue**, not only in science, but in life as a whole. Structure is often treated as being static and more or less complete in itself. But a much deeper question is that of how this structure originates and grows, how it is sustained, and how it finally dissolves. Structure is basically dynamic, and should perhaps better be called *structuring*, while relatively stable products of this **process** are *structures*. But even these latter structures should not be considered as basically static, for they are the results of **processes** which sustain them and keep them, for a **time**, more or less within certain **limits**.

"As with order, so with structure there can be no complete definition. Rather,... whatever we say structure is, it isn't. There is always something more than what we say and something different. At any given stage, it is possible to abstract a certain structure as relevant and appropriate. But later, as the **context** is made broader, the **limits** of validity of this **abstraction** are seen and new notions developed" (1987, p.141-2).

3242

STRUCTURE GENESIS (Law of)²⁾

"Any **process** of **communication** among the **components** of a system, once initiated and maintained with some regularity, leads to the genesis of **social structure** among **communicators** within the system" (K. KRIPPENDORFF, 1986, p.43).

According to KRIPPENDORFF, "the law presupposes that the individual **components** exhibit some regularities (e.g. conditional preferences, statistical biases in response to **stimuli**, rational **behavior**) and participate in the system for some **time**. The speed of structural genesis increases with the **complexity** of the **communications**, with the number of participating **communicators**, and with the length in **time** of the **process**. The speed decreases with the **level** of awareness and the number of **messages** controlled by each **communicator**. However, the law holds irrespective of whether the result is anticipated or desirable" (Ibid).

Structural genesis can be related to various other systemic viewpoints. One is CHRISTALLER's theory of **hexagonal space filling organization**. Another is C. LAVILLE concept of **vortexes**. Another one is V. CSANYI's theory of **autogenetic organization** and still others, the recent D.K. HUTCHINS' **configuration entropy** concept and D. Mc NEIL's **model of toroidal organization fields**.

3243

STRUCTURE SYSTEM²⁾

(In **reconstructability analysis**) "A collection of (sub)systems with consistent **distributions**" (A. RAMER & L. LANDER, 1990, p.448).

The authors comment: "When interested primarily in the **relationships** among the **variables**, rather than the **distributions** of their values, we speak of structure systems simply as structures. (A structure system can also be introduced in terms of behavior systems or state-transition systems (KLIR, 1985)" (in KLIR, 1985; RAMER & LANDER, p.448)

"A structure is covering if the union of its **elements** contains all the **variables** of the system" (ibid).

3244

STRUCTURE TRIGGER^{1) - 2)}

Some **noise** in a system that reveals a hidden potential **order**.

R. VALLÉE argues that **noise** cannot *create* **order**, but that it can make visible some **implicit order**. This is the case "when, because of a variation of some **parameter** defining the **dynamics** (of a system), it reaches a **unstable equilibrium state**, where a variation, even very small, of its **state**, produced by some **environmental perturbation** (i.e. a **noise**), throws it in one of the possible evolutive branches at that **bifurcation point**" (1992c).

This is consonant with the so-called order from noise principle, as exemplified by von FOERSTER's box of disordered magnets, which however conceals potential order. It is also related to PRIGOGINE's **nucleation**.

3245

STRUCTURE: VARIABLE OR INVARIANT?¹⁾

The variable or invariant character of a system's structure is a subject of controversy since long (see for example J.L. LE MOIGNE, 1977, p.160-163).

It is now generally admitted that a structure is **diachronic** as well as **synchronic**: each of its instantaneous **states** is a peculiar aspect of its temporal **totality**.

In a mature system, only feeble **variations** of the structure remain possible and one comes quite close to **invariance**. There are however at least two special cases to consider:

- A growing system undergoes frequently significant structural changes (examples are the moult of insects or the **transformations** of an **organization** at its beginnings). However the basic structure is then already a finited **matrix** of the **set** of all possible instantaneous structures (the larva of a mosquito will never produce anything else than a mosquito).
- A **system faraway from equilibrium** and submitted to giant **fluctuations** tends to transform itself and its structures through

the **emergence** of **dissipative structures**. In such case the **emergence** of a new system, quite different of the original one is a distinct possibility. The new system would then be structured in a more complex way than the former one.

3246

STRUCTURES (Five Proposals on Organizational)⁴⁾

The following five proposals by H. BOUCHIKHI result of his study of the **process** of introduction of personal computers in the "Régie Autonome des Transports Parisiens" and are thus related to administrative **structuration** (1990, p.428-35).

It would be interesting to look for **isomorphies** in biological systems and in animal societies (See "**stigmergy**").

- "1. **Organizational** structures are a **set of rules** and **resources** *recursively* engaged in the **structuration** of **organizations**
2. **Organizational** structures are simultaneously medium and result of the **interactions** among participants
3. **Organizational structuration** expresses a dialectic **process** of **equilibrium** between the **organization** and its **environment**
4. **Organizational** structures are closely linked to the **cooperation** and competition stakes of the participants

Figure: see entry **STRUCTURES of a SYSTEM (Basic)**

5 **Organizational structuration** results of a multitude of local **processes** not all necessarily convergent".

BOUCHIKHI makes different interesting points:

- a) **Organizational** structures are not rigidly imposed "from above" (or should not be!)
- b) **Organizational structuration** do not result in a static structure, achieved once and for all;
- c) Being the product of a **process**, it proceeds dynamically, by progressive propagation
- d) **Organizational structuration** is not necessarily a conscious **process**
- e) **Organizational** structures are not abstract; they result of the permanent **activity** of individuals

The following comment in a not-related paper by M. BUNGE (1988, p.7) seems opportune: "Interestingly enough, **cohesion** turns out not to be proportional to overall participation. Instead, it is maximal for middling participation – which is reasonable, since nil participation is incompatible with communality, whereas the participation of everyone in everyone else's affairs results in **anarchy**".

3247

STRUCTURES of a SYSTEM (Basic)²⁾

J.de ROSNAY enumerates thus the basic structures of any system:

Illustrating some organizational structures.
From M. KOCHEN: 1957, p. 37

- **Elements** or **components**, that can be counted and assembled into **categories**, families or **populations**: molecules, **cells**, inhabitants, machines, goods

- A **limit**, that defines the borders of the systems and separates it from the external world: **membranes**, the hide, the borders of a country

- **Stores** into which **elements** can be collected and wherein **energy**, **information** or **matter** may be kept: **organs**, tanks, computer memories, libraries, films

- A **communication net**, that permits exchanges of **energy**, **information** or **matter** among the systems **elements** or **stores**: nerves, arteries, roads, canals, cables, pipelines, etc..." (1990, p.98-9).

There are generally different kinds of **elements**, **subsystems**, **stores** and **communication nets** in a system. (**Elements** can constitute ordered **subsystems** of different types).

As to the **limit**, or border, it is as much an exchange structure as a **separator**.

see figure page 566

3248

STRUCTURES (Types of)²⁾

Two basic types of structures seem to appear in all classes of systems:

- Cellular structures, as for example in crystals, vegetal tissues, beehives, and **hexagonal organization** in human occupancy of space.

- branching structures in electric discharges, growing crystals, trees, **neuron networks**, and **hierarchic organization** in human systems.

Cellular structures seem to result from strong **environmental constraints** leading to an **involution process**.

Branching structures, result of oriented **bottom-up** or **top-down processes**, with **constraints dominant** in a favored direction. Branching structures can be mathematically modelled by **anastomic networks**.

These structures appear to be mostly stable, at least at the human **level of perception**. In fact, when they maintain themselves, it is through permanent **self-reproduction**.

A third class of structures are the interconnected looped structures, characteristic in **complex systems**, wherein **rules** controlling the numerous possible **interactions** lead to (generally imperfect) **organizational closure**, with more or less periodic (or **chaotic**) **self-reproduction**. This type of structures has been researched by M. KARSKY (1993, p.1412-21).

This author applied the looped structures **model** to what he calls "**delayed catastrophes**".

3249

SUBJECT³⁾ - 5)

"A purposeful individual or system" (R.L. ACKOFF & F.E. EMERY, 1972, p.34).

According to F. FRISCHNECHT and J.P.van GIGCH: "subject" generally represents any natural or artificial **entity** (e.g. **cells**, **organs**, **organisms**, human beings, social **groups**, institutions, computers) capable of *processing*, i.e. manipulation" (1989, p.240).

A subject is thus an active, more or less **autonomous entity** (even if **part** of an **entity** of higher **level** which may **control** it through an **order parameter**, in the sense of HAKEN **slaving principle**)

Human subjects are self-defined. They have viewpoints as **observers**. They relate to each others through **conflict**, **cooperation**, **consensus**, etc...

3250

SUBJECTION¹⁾ - 2)

"A governing **relation** of **asymmetrical dependence**" (J. FEIBLEMAN & J. FRIEND, 1969, p.36).

This is basically the **hierarchical mode** of **organization** of systems, in which the **survival** of some **elements** depends on other **elements** or **subsystems**.

For example, partial destruction of the nervous system or the **brain** leads to the loss of certain **functions** in the **living system**. In a somewhat similar sense, in an authoritarian society, the welfare and even at times the **survival** of the citizens depends on the **group** which controls the state.

The concept of subjection seems quite similar to the one of **slaving** in HAKEN's **synergetics**.

Asymmetry is not necessarily absolute, since what happens in the system depends on the relative position of the intervening **elements** in the **hierarchical order**. For example, a living being which loses a leg may survive, but its potential for action decreases heavily.

3251

SUBJECTIVITY (Epistemological)²⁾ - 3)

Condition of an observing and acting system which ascribes some of its own properties to the objective **universe** of which it is a part.

R. VALLÉE describes this condition in a more rigorous manner: "Through a **process** of "**inverse transfer**", induced by the reciprocal image **operator** $y \cdot 0^{-1} y$ (identifiable with the **inverse operator** when it exists, so when 0 is bijective), the properties of the functional image space (**topology**, **order**, **measure**...) are arbitrarily attributed to the **space** of all the possible original **evolution functions** x , generating what we can call the epistemological subjectivity of the system" (1990b, p.39).

It is interesting to note that, in the case of **conversation** in G. PASK mode, or **2nd. order cybernetics** of von FOERSTER, **consensus** when established does not define anything more than a domain of shared epistemological subjectivity.

It is obviously the opinion of these same authors.

3252

SUBLATION²⁾

The **hierarchical nonsymmetric** negation.

According to H. SABELLI, who transfers the term from dialectics: "It implies **evolution** in **time** and **similarity** between the terms of the contradiction. The opposition of the two terms of the contradiction is transient, their unity is essential and becomes permanent in a consistent and complete synthesis. The relation between thesis and antithesis and in the same manner the antithesis is sublated by the synthesis. Each term creates new properties by conserving, transcending and superseding the other terms" (1984, p.352)

3253

SUBSTITUTION (Forced)⁴⁾

A **process** in an **organization** through which the highest **decision maker** forces some definition or **action** upon the **organization**, because of the lack of useful **response** of the members of the **organization** to some challenge.

In some extreme cases, it is the **decision maker** himself who is substituted, as in political or military coups. When the challenge is putting the **organization** in danger (or seems to do) the forced substitution is a quite common reaction. As the substitute authority has generally no better **understanding** than the one it replaces, the results are seldom satisfactory, specially in a **long-term** perspective, even if in some extreme cases it can be the only way to avoid great losses, or even total destruction. Forced substitution reflects indeed a very serious flaw in the **organization**.

In effect, the real and permanent challenge is to enable the **stakeholders** in the **organization** to understand and accept their responsibilities and give them the means to do so.

Only **Generic Design** (WARFIELD), or **Unbounded Systems Thinking** (MITROFF and LINSTONE), or **Co-participative design** (Fuschl Group), or similar **methods of design** or **management** can prevent this class of disorders.

3254

SUBSTRATE¹⁾

The basic grid or ground on which a system can be constructed or self-organized.

The substrate must have some specific characteristics which makes it proper for the **development** of the system as for example be **homogeneous** or **isochronous**, or isometric, or **isotropic**.

A good **model** of a substrate is the squared grid on which CONWAY's **Game of Life** can be developed. There are also physical substrates, as in **catalysis** or crystallization **reactions**. Substrates can be illimited, but only in theory. Observe the difference with the **rules** of chess, in which the movement **rules** of the various chessmen makes the chessboard different for each kind.

3255

SUBSTRUCTURE ¹⁾ - 2)

A **structure** of a **subsystem**.

Substructures are normally correlated to each other at the same **level** of **complexity** and, at the same time, in a relation of subordination to the global **structures** of the system.

3256

SUBSUMPTION ¹⁾ - 3) - 4)

The ordering of a **set** of **concepts** in a hierarchical unity.

J. WARFIELD states: "Subsumption is relevant not only to the **organization** of **knowledge** in ways that facilitates its interpretation and utility, but also to **components** of **organizations**" (1990, p.290).

And: "Subsumption replaces "interdisciplinary", "aggregative", or "integrative", in **situations** involving the bringing together of all available relevant **knowledge** to **construct** a new organic **conceptual whole**" (pers. communication, 1991).

"(Subsumption) places no artificial limits on the sources of the **concepts** to be **aggregated** and thus admits actors to the discussion who are not obsessed with "disciplines". At the same time it allows for the possibility that an area of interest which has achieved subsumption of relevant **knowledge** to a high degree of quality may still be called a "discipline" in the academic sense" (1990b, p.290).

Remains to hope and see if obstinate "disciplinarians" will be heedful!

Subsumption must "increase the scope of the **model** without removing its previous **content**. Movement such as this is an antidote to the disease called "hardening of the **categories**", which is often found as a glue that holds inadequate **frames** in place" (WARFIELD, 1989, p.16).

And: "A **subsumptive transformation** implies bringing together diverse views and ideas and transforming those by **aggregating** them and **integrating** them into a new and more encompassing perspective" (1990a, p.69-70).

→ **Supersumption**

3257

SUBSUMPTION ARCHITECTURE ¹⁾ - 2) - 5)

The construction of complex **behaviors** in robots, by **interactions** of simpler ones.

This concept has been introduced by R. BROOKS (1989), and is based on the belief that intelligence does not necessarily needs reason.

According to BROOKS, "... complex **behavior** becomes possible in a robot only when there are simpler **behaviors** present that it may subsume" (A.K. DEWDNEY, 1992, p.19).

P. WALLICH states that "complex **behaviors** such as exploration of the **environment** are built up from simple ones like moving a single leg..."

In this way it is possible to avoid "the conventional A.I. impasse of trying to construct and maintain a consistent logical **model** of the outside world" (1991, p.86).

Considering the **complexity** of the "outside world", it is now obvious that, in the present state of the art, it would be almost impossible to construct an efficient general **algorithm** into an **automata**. Furthermore, even in man, rational intelligence is neither needed nor used in many basic **behaviors**.

3258

SUBSUMPTIVE TRANSFORMATION ²⁾ - 4)

"(The) bringing together (of) diverse views and ideas and transforming those by **aggregating** and **integrating** them into a new and more encompassing perspective" (1990a, p.60-70).

J. WARFIELD and M. AYIKU state: "In seeking a subsumption transformation, three fundamental assumptions are involved:

- the assumption of **continuity**:... people will not relinquish an internalized long held **framework** discontinuously... Consequently, any new **framework** that is proposed must *subsume* (i.e. incorporate, but go beyond) the old **framework**
- the assumption of increased cognitive burden:... Since the new **framework** subsumes the old one, it necessarily involves increased cognitive burden because it incorporate more concepts and requires a new **web** of **interactions** among them to permit adequate interpretations.
- the assumption of necessary cognitive enhancement:... If the burden of **cognition** is increased, then there must be provided means of enhancing cognitive capability in order to compensate for the increased burden" (1989, p.27 - abridged).

This is very important for **systemics**, which produce indeed an "increased cognitive burden" and seems at times to break **continuity** with long hold conceptual **frameworks**. The authors have put their fingers on some of the main difficulties to communicate **systemic viewpoints**.

3259

SUBSYSTEM ¹⁾

"An **element** or functional **component** of a larger system which fulfills the conditions of a system in itself, but which also plays a specialized role in the **operation** of the larger system" (V. CSANYI, 1993, p.67).

According to CSANYI, subsystems are "...communities of simultaneously **replicating components**".

The subsystem is thus simultaneously an **interacting component** in a **suprasystem** and in its own right a system made of **interacting components**.

This author explains that subsystems result in a progressive way from the increase of specific and different **replicative cycles** during the **process** of **autogenesis** in the recently shaped system: "Their **components** are separated from others by their participation in **co-replication**". He adds that: "As **time** passes, **replicative coordination** of various supercycles develop and fidelity of **replication** increases" (1993, p.263) As a result, functional **differentiation** and **cooperation** grow on par.

CSANYI's "supercycles" are the primeval form or M. EIGEN's **hypercycles**, which are thus stabilized supercycles.

A subsystem can in most cases be clearly recognized because it performs a specific **function**.

Subsystems are generally made of numerous **components**. As a rule, they interact with each other in specific ways. They frequently exchange their products and the **output** of one of them may be an **input** for another.

Most of them are critical for the system: the demise of one of them generally brings along the destruction of the whole system within a short **time**. This is specially true when the system is strongly **integrated**.

M. BUNGE observes: "If a system does have subsystems, not just **components**, then the **cohesion** of the subsystems competes with that of the overall system" (1979, p.37). This may explain why, in very **complex systems** whose global **coherence** is costly and difficult to maintain, some subsystems may turn more or less **parasitic** of their own system: Bureaucracy could be an example.

3260

SUBSYSTEMS (The 20 critical) ¹⁾ - 2)

James G. and Jessie MILLER describe in the following way the 20 critical subsystems in **living systems** (1990, p.159):

Subsystems which Process both Matter Energy and Information

1. **Reproducer**, the subsystem which is capable of giving rise to other systems similar to the one it is in.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2. **Boundary**, the subsystem at the perimeter of a system that holds together the **components** which make up the system, protects them from **environmental stresses**, and excludes or permits entry to various sorts of **matter-energy** and **information**.

Subsystems which Process Matter-Energy

3. **Ingestor**, the subsystem which brings **matter-energy** across the system **boundary** from the **environment**.

4. **Distributor**, the subsystem which carries **inputs** from outside the system or **outputs** from its subsystems around the system to each **component**.

5. **Converter**, the subsystem which changes certain **inputs** to the system into forms more useful for the special **processes** of that particular system.

6. **Producer**, the subsystem which forms stable associations that endure for significant **periods** among **matter-energy inputs** to the system or **outputs** from its **converter**, the materials synthesized being for **growth**, damage repair, or replacement of **components** of the system, or for providing **energy** for moving or constituting the system's **outputs** of products or **information markers** to its **suprasystem**.

7. **Matter-energy storage**, the subsystem which retains in the system, for different **periods of time**, deposits of various sorts of **matter-energy**.

8. **Extruder**, the subsystem which transmits **matter-energy** out of the system in the forms of products or **wastes**.

9. **Motor**, the subsystem which moves the system or **parts** of it in relation to **part** or all of its **environment** or moves **components** of its **environment** in relation to each other.

10. **Supporter**, the subsystem which maintains the proper spatial **relationships** among **components** of the system, so that they can interact without weighting each other down or **crowding** each other.

Subsystems which Process Information

11. **Input transducer**, the **sensor** subsystem which brings **markers** bearing **information** in to the system, changing them to other **matter-energy forms** suitable for transmission within it.

12. **Internal transducer**, the sensory subsystem which receives, from subsystems or **components** within the system, **markers** bearing **information** about significant alterations in those subsystems or **components**, changing them to other **matter-energy forms** of a sort which can be transmitted within it.

13. **Channel and net**, the subsystem composed of a single route in physical **space**, or multiple interconnected routes, by which **markers** bearing **information** are transmitted to all **parts** of the system.

14. **Timer**, the subsystem which transmits to the **decider** **information** about **time-related states** of the **environment** or of **components** of the system. This **information** signals the **decider** of the system or **deciders** of subsystems to start, stop, alter the **rate**, or advance or delay the **phase** of one or more of the system's **processes**, thus coordinating them in **time**.

15. **Decoder**, the subsystem which alters the **code of information input** to it through the **input transducer** or **internal transducer** into a "private" **code** that can be used internally by the system.

16. **Associator**, the subsystem which carries out the first stage of the **learning process**, forming enduring associations among items of **information** in the system.

17. **Memory**, the subsystem which carries out the second stage of the **learning process**, storing various sorts of **information** in the system for different **periods of time**.

18. **Decider**, the executive subsystem which receives **information inputs** from all other subsystems and transmits to them **information outputs** that **control** the entire system.

19. **Encoder**, the subsystem which alters the **code of information input** to it from other **information processing** subsystems, from a "private" **code** used internally by the system into a "public" **code** which can be interpreted by other systems in its **environment**.

20. **Output transducer**, the subsystem which puts out **markers** bearing **information** from the system, changing **markers** within the system into other **matter-energy forms** which can be transmitted over **channels** in the system's **environment**.

In J.G. MILLER's original versions (1965, 1978), only 19 critical subsystems were described. The 20th., i.e. the "timer" was introduced by J. and J. MILLER (1990)

Note: The 20 critical subsystems are registered in their own alphabetic order in this encyclopedia.

3261

SUMMATION TIME^{1) - 2)}

"... a finite **period** of grace... such that two pulses arriving within such a **time period** still act as if they had been **simultaneous**" (J.von NEUMANN, 1958, p.55-56).

von NEUMANN defines summation time in relation to the transmission of **simultaneous** nervous impulses. A curious consequence is that *perceived simultaneity* is somehow slightly sequential. Summation time is thus necessary for any coherent global **perception**, even if supposedly **simultaneous**.

This is an interesting view, if connected with the concept of **parallel processing**: the interconnection of sequences processed in parallel is necessarily *somewhat* sequential!

3262

SUMMATIVITY²⁾

Process in which the "...variations of any **element** depend upon that **element** alone and **variations** of the **whole** system represent a sum of **variations** of its **elements** taken independently of each other (there is no **interaction** in this case)" (I. BLAUBERG et al., 1977, p.54-55).

This concept seems self-defeating. If the system "is more than the sum of its **parts**" the existence of **interactions** is indispensable and obvious. Conversely, if there are no internal **interactions**, but only an array of unconnected **transformations** of **elements**, there is no system.

The situation of simple summativity does not even seem to exist in **composite systems**, wherein at least there are global statistical **interrelations**.

3263

SUNK-COST FALLACY¹⁾⁵⁾

"The human tendency to judge options according to the size of previous investments rather than the size of the expected return" (P. AYTON & H. ARKES, 1998, p.40)

The authors state: "Truly rational **choices** would be made only after weighing up future **costs** and benefits. Past **costs** and benefits are quite irrelevant" (Ibid)

To let oneself into the sunk-cost fallacy leads to "throw good money after bad", i.e. to transform a still available **resource** into a highly probable loss.

This **behavior** can easily be observed in the stock market. It was also the irrationality that dominated the Vietnam war and led to this tremendous fiasco.

3264

SUPER-, SUPRA-¹⁾

Two prefixes used to generally indicate a higher **level** in **concepts**, **models** and **systems**.

These are practically undistinguishable synonyms.

3265

SUPERCYCLE¹⁾

An original incipient **replicative cycle** that appears during the **autogenetic process** of a system.

According to V. CSANYI who introduces the concept, supercycles appear if there is at least one **cycle** of **component-producing processes**, duly activated by **energy inputs** when the **autogenetic process** sets in, eventually generating a full-blown **autopoietic** system.

In **time**, different **replicative** supercycles become more stable and originate cyclically interrelated **subsystems**. At that **stage**, they can be assimilated to M. EIGEN's **hypercycles**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3266

SUPERORGANISM¹⁾

"An insect society that possesses features of organization analogous to the physiological processes of individual organism" (Th. SEELEY, 1989, p.548).

The term was coined by W.M. WHEELER (1919). It was a forerunner of the **organismic** viewpoint and of **self-organization** and **dissipative structuration models**.

3267

SUPERPOSITION (Principle of)²⁾

J. MILSUM enounces: "The principle of superposition states that a system responds to each of several **inputs** as if the others were not present" (1968, p.10)

This could be totally true only in **linear systems**, i. e. systems not interconnected in a complex way.

3268

SUPERSUMPTION^{1) - 3)}

"The ripping away of a concept from its proper place in a **context**, and elevating it to undeserved status" (J. WARFIELD, 1991, pers comm.).

This is the opposite of **subsumption**.

WARFIELD uses the example of the so-called "economic man" as the not otherwise qualified subject of economic science, thus supersuming one particular aspect of men's **behavior** and "thereby perpetuate a defective, arbitrary defined, set of ideas about human **behavior**" (1990 b, p.291).

→ **Subsumption**

3269

SUPPORTER^{1) - 2)}

"The **subsystem** which moves the system or **parts** of it in relation to part or all of its **environment** or moves **components** of its **environment** in relation to each other".

This is one of the **20 critical subsystems** in J.G. MILLER **taxonomy of living systems** (1978, p.3).

3270

SUPRA-HUMAN SYSTEMS¹⁾⁴⁾

This notion has been introduced by F. ROBB (1992)

According to ROBB very vast and developed human systems escape essentially out of the **control** of their individual participants.

While such supra-systems are initially **bottom-up** constructions they end up exercising a **top-down** control on their participants.

The following reasons seem significant:

- statistically, each member of the society is practically powerless at the supra-level. He is just carried along by the massive **flow** of

the famous "silent majority", even if that flow reflects merely a **herd-effect** (the so-called "public opinion")

- structurally, the individual member find himself generally closely encased (and even ensnared) within some **social structure** (institution, **organization**, business) that he has been more or less obliged to join to prosper (or simply survive) personally
- the two former aspects have systemic undertones: mainly, SABELLI's principle about "**priority of the simple, supremacy of the complex**" traduces itself as a fundamental **dissymmetry** between levels in highly differentiated complex systems.

The general impotence of the isolated individual explains probably the existence of lobbies, pressure-groups, cartels, and even mafias which are **coalitions** of individuals trying to recuperate or obtain some control on society. Of course in such cases **symbiosis** turns into **parasitism**.

Anyhow, modern mass-societies are becoming more and more similar to global **self-organizing automata**.

→ **Cross-level research; Crowding effects; Dissipative structuration; Institutionalization; Network (Evolutionary); Proxemics; Superorganism**

3271

SUPRASYSTEM¹⁾

A system of higher **order** in relation to some systems or **subsystems** of lower **order**.

While sometimes confused with "**metasystem**", it seems more related to **models of concrete systems**.

K. BERRIEN proposed some criteria for characterization of the suprasystem:

"Systems may produce useful or useless **outputs**, as determined by the suprasystem.

"Suprasystems select the **outputs** of their **subsystems** which are useful; contrarywise, the suprasystem rejects useless **outputs** from its own **subsystems**" (1968, p.33).

BERRIEN also considered that the **universe** could be represented as a **nesting** of systems, within systems, within systems; etc... Furthermore, the emergence of suprasystems corresponds to new **levels of emergence of complexity**. This view was later on confirmed by PRIGOGINE's **emergent dissipative structurations** at **bifurcation** points in systems **far from thermodynamic equilibrium**.

It also corresponds to J. STULMAN's concept of **fields** within **fields**, within **fields**... (1968-75)

R. VALLÉE writes: "...it is not surprising that the consideration of the pair **subject-object**, or **subject-subject**, that is to say of a super-system, at a **meta-level**, can bring great conceptual simplifications. This super-system, or **universe**, has the great advantage of being the one and only system to possess no border and,

hence, no **environment**" (1992d, p.26). This total **universe** is however purely theoretical. The concept can be used only in a willful manner by deciding that the chosen super- or supra-system escapes from **Gödelian** limitations, i.e. by suppressing any supra-supra system, at the eventual risk to run into logical contradictions.

B. BANATHY gives a different definition of the suprasystem: "A system made up of a number of **component** systems" (1973, p.88).

The terms "**supersystem**" and "**metasystem**" also appear frequently in systemic literature, in a very close sense.

Obviously, many authors sensed this kind of **hierarchical** or **embedding** relation, in somewhat different shades of meaning and it should be very difficult and even inappropriate to decide in favor of one or another.

We should merely propose to use "**metasystem**" in the sense of "controlling, or relevant **environment**", while the "suprasystem" (or "supersystem"), in a somewhat different sense, should be the global **environment** of its **component** systems.

This is of course also debatable, because it is then no more than a system of higher **level**.

According to BERRIEN, an important property of the suprasystem is that it "... can slough off some noncontributing **subsystems** and encapsulate or generate replacements" (1968, p.85).

BERRIEN wrote that this is precisely a property of biological systems. It seems to be extensible to **social systems**.

3272

SURROGATE WORLD¹⁾²⁾

A constructed **model** of a factual **situation**.

This important concept has been introduced by St. BEER (1973), who described the fictional way in which models are used by many people. BEER writes: "The model intervenes between the manager and the situation. It must do this: it is a kind of **filter** intended to cut out **noise** and enhance **perception** of meaningful **patterns**" (p. 199)

Of course, as explained by BEER, two very serious problems appear in many cases:

- "the model may be no good". This is because it depends on the **mental frame** or **reference frame** of the **modeller**, which may be incomplete, inadequate and /or distorted
- "people often begin to mistake the model for the **reality**- and start managing the model instead" (ibid)

Obviously, reality follows its own course meanwhile, either impervious to our mirage, or worse, reacting to it in an unexpected way

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Many mistakes and even disasters in business, economy, politics and generally human affairs do result of this kind of misguided use of models which are not recognized as incorrect surrogates

→ **Model**

3273

SURVIVAL (Conditions of)¹⁾

There seems to be two basic conditions for any systems survival:

- maintain its basic adaptive **fitness** within its specific **environment**;
- maintain its internal **organization**, and specially its **organizational closure** and internal **regulations**.

Of course, its **environment** must be sufficiently **stable** as to spare it unconquerable challenges.

3274

SUSTAINABILITY¹⁾⁴⁾

Any sustainable **process**- and still more so any **complex system**- depends obviously from the use of the **resources** in such a way as not exhaust them.

Sustainability cannot be maintained for ever through **linear processes**. In fact it is necessary based on the **interdependence** in the **relationship** of the process or system with its significant **environment**.

Runaway processes are particularly dangerous for sustainability, which can generally not be restored after such episodes.

Many present economical and ecological processes are obviously unsustainable at **long**- and possibly even at **medium-term**. If the need for permanent balanced re-equilibrated **feedbacks** with their input sources, for example by **recycling**, is not understood in due time, **collapses** could become unavoidable

3275

SUSTAINABILITY (Supply side)²⁾

T.F.H. ALLEN, who developed this **model** recommends the following steps (**hierarchically** organized), to create the general conditions for sustainability in **complex systems**:

- manage for whole **ecosystems**, not **resources**
- manage from the **context** to facilitate internal functioning: the healthy **ecosystems** in context subsidize the effort
- use **positive feedbacks** to achieve systems **change** (1998, p. 4)

In short, sustainability of **processes** must be subordinated to the system's sustainability

which in turn can be maintained only through a permanent **symbiosis** of the system with its **environment**.

Of course such a symbiosis implies some aspects that frequently remain hidden, as for example:

- the system's **outputs** must be carefully managed in order to avoid spoiling the environment
- technical **change** can (and generally does) modify the balance between the system and its environment. Such a change should be carefully scrutinized. Indeed a **change** can be initially beneficial and turn negative in the long run or it may be costly at the beginning and become positive later on
- the use of positive feedbacks to achieve systems change should be cautious, lest they lead to a global and possibly irreversible loss of **dynamic stability**, i.e. **long term** sustainability

3276

SUSTAINABLE^{1) - 4)}

Character of a **process** that can be maintained in a permanent way.

A systemic **process** is sustainable in this sense if a regular and permanent **input** of needed **resources** is guaranteed and if the **process** does not end up choked by its own products.

In M. DODDS and G. JAROS words: "... the **environment** is not a neutral laboratory but a **stakeholder** with needs of its own" (1994, p.14).

The chances for a **process** to remain sustainable are poor if it uses up an ever growing quantity of **critical inputs**: such a **situation** normally leads to scarcity or exhaustion of the **resource** and asphyxy of the **process**. Thus only **steady state processes** can be sustained *in the long run*, normally after a progressively slowing down **growth phase**.

This is a very important practical notion for any systemic **process** of **development**.

→ "**Economics in systemic terms**".

3277

SWAMPING^{1) - 4)}

The overwhelming of a **signal** by a much more powerful one.

This is the case for overlapping radio **signals**, when the more powerful one drowns the feebler one.

Analogically, a mass belief drowns the less powerful opinions of minorities or individuals, either by suppressing them in a definitive way, or by covering their voice until relenting. Recent examples are the resurgence of long swamped religious practice or local nationalisms in the former U.S.S.R.

3278

SWARM^{1) - 2)}

A large group of **elements**, with a more or less organized collective **behavior**.

In nature, insects form swarms. Fish shoals are also swarms. In both cases the formation of the swarm results from reciprocal **perception**. The swarm is probably the most elemental form of **sociosystem** and corresponds to some benefits individuals obtain from close proximity in the swarm, as for example relative protection against predators.

→ **Bottom up; Dictyostelium discoideum; Herd effects; Intelligence (Distributed artificial); Parallel distributed processing; Pheromone; School; Shoal; Sociality; Somatic ecology; Stigmergy**

3279

SWARM INTELLIGENCE¹⁾⁴⁾

The capacity of a number of interacting simple **elements** to developed coordinated **group behavior**.

L. STEELS (Brussels Free University) explores "**swarm intelligence**", i.e. coherent **emergent** collective **behavior** in **groups** of artificial and individually **autonomous agents**. Using BROOKS' **subsumption architecture** as a tool for functional **self-organization**, he defines a kind of *robots ecology* (1990).

The **methodology** used is akin to collaborative **communication**, based on pheromones, in social insects. Each participant needs only reduced **perception** and **decision** capacities: global **organization** appears spontaneously through **communication**.

The terms "swarm intelligence" were introduced by DENEUBOURG et al (1992). It related however in this context to "the **simulation** of the termites nest-building **behavior** on a computer by applying a very simple "**stigmergic algorithm**".

J. HOFFMEYER criticized this view: "I am not going to defend the view that the collective behavior of termites deserves to be called intelligence" (1995, p. 20). while this is semantically commendable, it seems to miss the point. Hoffmeyer himself describes the process as "distributed **problem solving**" (ibid). As such, swarm intelligence, being it in insect societies, **robots**...or of course human societies is basically a **communication process** in which the individuals take part each in accordance with its **perceptive** possibilities, and **decision** and **action** ones. They could be considered as a discontinuous collective **boundary** between the swarm (or system) and its **environment**.

Swarm intelligence is now modeled by groups of **robots** whose individual cognitive abilities are very limited, but who may become able to execute complex tasks by interacting in accordance to some **rules**. (A. MARTINOLI et al., p. 56-62, 2002)

Moreover, these **interactions** are triggered by specific **events** in the **environment**.

The main concepts of swarm intelligence have been derived from the **observation** of social insects (ants, bees) and fish **schools**. Two basic conditions seem to be indispensable.

- 1) The existence of a **perception** capacity for some well specific conditions, **forms**, or **activities** in the environment
- 2) The existence of a specific **mode** of **communication** as for ex. **pheromones** or electromagnetic **signals**

Human societies have evolved high level swarm intelligence through very differentiated and precise capacities of perception and communication systems (a **variety** of coded natural or technical **languages**). Moreover, all such processes depend on **learning** and transmission through **time** or registered results (i.e. some form of **memory**)

→ **Algorithm; Algorithm (Back-propagation); Bottom up; Cybernetics (2nd); Dictyostelium discoideum; Herd effects; Intelligence (Distributed artificial); Parallel distributed processing; Pheromone; School; Shoal; Sociality; Somatic Ecology; Stigmergy**

3280

SWIRL ²⁾

An eddy, **vortex**, whirl, or whirlpool.

A sometimes used synonym for a gyrating or spiraling movement in two or three dimensions. Swirls are generated by interacting **fields**

3281

SWITCHING ^{1) - 2)}

The crossing of a system or **population** from one **domain of attraction** to another.

As to **populations**, C. HOLLING explains: "It has indeed been found that fecundity and mortality will generate **domains of attraction**, with each domain separated from other by characteristic extinction and escape **thresholds** (1965).

"As long as the **populations** remain within one **domain**, they have a consistent and regular form of **behavior**. If they pass a **boundary** to the **domain** by **chance** or through intervention by man, then the **behavior** suddenly changes..." (1976, p.80).

A similar situation has been shown by H. LABORIT in physio-psychological **processes** switching from resistance to submission, or conversely (1954, p.3).

→ "Catastrophe"

3282

SYLLOGISM (Bayesian)

→ **Bayesian syllogism**

3283

SYMBIOGENESIS ¹⁾²⁾⁴⁾

(This replaces the existing entry)

The **emergence** of a higher form of **organization** as result of growing **symbiosis** between two (or more) different systems.

P. CORNING (1998b, p. 23) establishes the priority of "an obscure school of the 19th and early 20th Russian botanists". He quotes MERZHKOVSKY who coined the term "sybiogenesis" and defined it as "the origin of **organisms** through combination and unification of two or many beings, entering into **symbiosis**" (1920, p. 65)

CORNING also quotes another russian theorist, B.M. KOZO-POLYANSKY who observed that: "The theory of sybiogenesis is a theory of **selection** relying on the physiology of **symbiosis** (1932,p.25) and in no way incompatible with Darwinian evolution".

F. CAPRA synthesizes in the following terms a basic discovery by Lynn MARGULIS: "The sudden appearance of nucleated **cells** in the history of **evolution** and the discovery that their organelles are distinct self-reproducing **organisms** led (her) to the conclusion that nucleated cells have evolved through **long term symbiosis**, the permanent living together of various bacteria and other microorganisms" (1997, p. 242) (Also L. MARGULIS, 1981, 1993) and L. MARGULIS & M. McMENAMIN (Eds.), 1993).

By an adequate combination of characters, complex sybiogenetic **organisms** can survive and evolve in conditions that would not be suitable for their **parts** in separate forms

CAPRA even observes that many old myths ("sphinxes, mermaids, griffons, centaurs...") seem to convey in an implicit way the idea of sybiogenesis. He adds: "Somehow the collective human unconscious seem to have known from ancient times that **long-term symbioses** are profoundly beneficial for all life" (Ibid, p.245).

It seems now that some new forms of sybiogenesis have surfaced in techniques. Many modern complex **artifacts** are results of the convergence, **co-adaptation** and final **integration** of a number of simpler techniques: the steel and the diesel motorships, the car and the aircraft are outstanding examples.

It seems even possible that a similar **phenomenon** plays a role in the **organization** of complex **social systems** and are still presently fully active (crf. the **globalization process**).

The more general systemic significance of the concept is obviously based on complementarity between compatible systems with benefits for both, until the fusion reaches **irreversibility**, i.e. when the individual **parts** cannot anymore survive independently.

The same concept also emerged in W. SCHWEMMLER's work (1991), together with a kind of operative **process model**, namely his **toolkit principle**.

3284

SYMBIONT ¹⁾⁴⁾⁵⁾

An **organism** that lives in close **relationship** with another one.

The symbiont's relation with its co-symbiont tends to become permanent and may lead to closer forms of **association**, including down-right **parasitism**, or complete fusion leading eventually to the **emergence** of a more **complex system** at a higher level of **integration**. (W. SCHWEMMLER, 1991, p. 97-99)

3285

SYMBIOSIS ¹⁾

"An exchange between systems in which a **part** of each system's **autonomy** is sacrificed in order to enhance a superordinate system **relationship**" (Ch. SMITH, 1986, p.209).

The term symbiosis was introduced by the german mycologist A.De BARY (1879)

In symbiosis, "one or more system may benefit and none are harmed" (UNESCO-UNEP, 1983, p.26).

Ch. SMITH comments: "The stronger superordinate **relationship** ultimately increases each of the original system's **resilience**..." and...

"Systems are observed to be more symbiotic and more communicative with other systems in their **environment** after a **dissipative transformation process**"

According to E. JANTSCH: "The **emergence** of pre-cellular, self-reproducing life forms is an example of a **dissipative change** that resulted in a symbiotic **relationship**. Two classes of molecules catalyzed each other's development by combining. Each molecule offered something that the other molecule did not have: the **best information** carriers joined with an excellent **catalyst** to make possible the preservation of a system and the development of a means of transferring complex information" (in SMITH, 1986, p.209).

M. MARUYAMA's **deviation-amplifying mutual causal process** is possibly a workable **model** of symbiosis, which has to see with opposite **complementarity** in **growth processes** (1963).

MARUYAMA also states: "... the basic principle of the biological and social universe is increase of diversification, **heterogeneity** and symbiotization. What survives is not the strongest, but the most symbiotic" (1976, p.202).

C. BRESCH has given a good embracing outline of symbiosis by **catalysis** in his book about **evolution** (1977).

R. DAWKINS makes the following - and somewhat startling - comment: "I speculate that we shall come to accept the more radical idea that each of our genes is a symbiotic unit. We are gigantic **colonies** of symbiotic genes" (1978, p.196).

The tendency to symbiosis may well be a generic feature of any **sociogenesis**, including for human societies.

Symbiosis is not to be confused with **commensalism**, nor **parasitism**.

Global **homeostasis** in very complex meta-systems (e.g. in economy, in ecology) may be understood as a result of the symbiosis of numerous participant systems.

In spite of the existence of various distinct and sometimes nearly conflicting definitions of symbiosis, P. CORNING states: "Nevertheless, there seems to be general agreement that symbiosis refers to the **relationships** of various kinds between biological entities and the functional **processes** that arise from those relationships" (1998b, p. 24). CORNING adds: "**Synergy** on the other hand, refers to the interdependent functional **effects** (the bioeconomic "pay offs") of symbiosis- among other cooperative **phenomena**".

Moreover, while "...all symbioses produce synergetic effects,...many forms of synergy are not the results of symbiosis" (Ibid p. 24-25)

Compare also with V. CSANYI **zero-system**.

3286

SYMBIOTIC PARTNERSHIP²⁾⁴⁾

The **association** of two or more distinct vegetal and/or animal species producing benefits and/or protection to both.

This seems to be a step previous to integrated **symbiosis**, or at least could be.

An example at a practically automatic **level** is the **reaction** of a tree, parasited by some insect. The tree emits **pheromones** as a response to the attack and these attract parasites of the parasite.

P. CORNING (2001, p.8-9) gives examples of symbiotic partnership. One is between the African honey guide bird, who discovers a hive and a badger, who is able to dismember it. The bird gets the beeswax and the badger eats the honey.

Corning also cites the partnership of the same honeyguide bird with the nomadic northern Kenyan Boran people, with similar results.

Symbiotic partnership also exist at the simplest biological level. Corning even gives an example of multiple partnership in a single-celled protist: *Mixotricha paradoxa*.

Symbiotic partnership, whatever its level or **complexity**, is clearly a socializing **mechanism**, leading to **living systems** of higher degrees of integrated **organization**.

It is however different in nature from **herd effects** or **swarms** which gather individuals of the same species, mainly for reciprocal protection.

3287

SYMBOL^{1) - 3) - 4)}

1. "A **sign** that would lose the character which renders it a **sign** if there were no interpretant" (C.S. PEIRCE, in J. HOOPES, 1991, p.240).

2. "A **sign** that is a potential producer of a **response** to something which in turn is a potential producer of a **response** to something other than itself" (R.L. ACKOFF & F.E. EMERY, 1972, p.168).

3. "Something that represents something else, by **association** or convention" (AMERICAN HERITAGE DICTIONARY, p.1302).

PEIRCE's definition is what makes symbols important in systemics: It shows the importance of abstract **frames of reference** in individual **observers** and in **communities**.

A symbol seems to be basically an individual and collective human **memory** device, useful to maintain **sociality**. S GOONATILAKE observes that "Cave pictures were the earlier cases of the externalization of internally kept **images**. In fact, the later development of writing is traced to pictographic roots" (1991, p.86).

ACKOFF and EMERY's definition seems to be rooted in C.S. PEIRCE's own and on his **descriptions** of the various types of symbols (J. HOOPES, 1991, p.30-1 and 240). They observe that, according to S. LANGER (1948), a symbol is a **sign** that signifies a concept, while CH. MORRIS used it as a **sign of a sign**.

Most symbols are created by deliberate **association**, but are thereafter transmitted by imprinting, a **process** whose roots can be found in animal **behavior**, as shown by K. LORENZ.

K. STEINBUCH has given an interesting **model** of symbol formation with his "**learning matrices**".

H. MALTA MACEDO states that symbols "are the fixed mental **structures** that holds against the shapeless everlasting **flow** of sense-**data**" (1992, p.674).

R. GLANVILLE observes that: "We make reference (create a temporary identity) between that which is to be communicated and that which is to communicate it (roughly and loosely, between **meaning** and **symbol**)" (1992, p.661).

Symbols generally transmit subliminal **messages**, once they become incorporated within a given culture.

Many symbols become supports for concepts, and can easily "be combined with other symbols" In such cases "A combination of symbols hence represents a potential **association** of concepts" (F. HEYLIGHEN).

Unfortunately the interpretation of symbols **significance** is not always stable nor clear and, furthermore they may easily be manipulated.

See hereafter about **semantic** confusion introduced by the restricted **signification** of "symbols" as something manipulated by computers.

3288

SYMBOLIC POWER⁴⁾

A psychologic pressure exerted by a dominant individual through some visible manifestation of his/her power.

This concept was developed by the French sociologist Pierre BOURDIEU (1930-2002).

In this way, displays of material wealth, acquired academic ranking, military uniform, etc... are used to impress other people in order to inspire them respect, obedience, etc.

Symbolic power seems to have roots in animal territorial or ranking displays and has probably also sexual **connotations**.

3289

SYMBOLIC PROCESSING^{2) - 3)}

D. GREGORY writes: "A great deal of mischief and unnecessary excitement has been caused through the use of the phrase *symbolic processing*. Symbolic processing, as distinct from number crunching is what powerful Lisp machines were manufactured for. The focus of the **distinction** is the realization that computers are not restricted to the manipulation of numbers, but rather, they can be made to manipulate any kind of symbol which may or may not represent a number. What is overlooked of course, is that the difference is a difference in *our* eyes only: the **machine** is in no position to care one way or the other whether what it manipulates appears to us as a number or a word. And it does not care because what it manipulates has no ultimate **meaning** for it.

"To a machine, the symbols it shunts around are **syntactic patterns**: it is only when a user interacts with the **machine** that the **patterns** are given some final symbolic value that finds existence at a **semantic** experience in the user".

"... It is the key to understanding how PASK's **cybernetics** is quite different to the A.I. enterprise" (1993, p.63).

In other words, by careless use of terminology, man puts unwittingly his own ghost in the **machine** and mistakes it for real.

3290

SYMBOLIC VIOLENCE⁴⁾

The psycho-sociological pressure exerted in an education or **training process** by the teacher on the learner.

According to P. BOURDIEU, symbolic violence tends toward the transmission of a worldview (*Weltanschauung*) proper to the educator as a member of a specific socio-cultural **group**. It corresponds to sets of **values** and **norms**, and also **perceptions** and feelings typical of such a group.

In most cases symbolic violence is implicit and even unconscious in the educator. It can however become overt and translate into more or less subtle discrimination or even declared ostracism against the individual that does not "conform" with the approved type or does not readily accept the **rules** established by the dominant group.

It is obviously a general and very basic feature in all societies and at all levels.

Snobism, ridiculization, **exclusion** from some circles, etc., are forms of symbolic violence.

It seems to be a mental form of the physical exclusion in social animals or insects based on **pheromonal** differences.

3291

SYMMETRY¹⁾

"The **relation** in which the interchange of the **parts** does not involve any **change** in the **relation**" (J. FEIBLEMAN & J. FRIEND, 1969, p.32).

On the contrary, **asymmetry** implies such a **change**.

FEIBLEMAN and FRIEND give the following example "...The **relation** of the skin of an apple to the flesh is not the same as the **relation** of the flesh to the skin, and is therefore an **asymmetrical relation**... (however) grains of sand are symmetrical since an interchange of **parts** does not involve any **change** in their **relation**" (Ibid.).

A better example of **asymmetry** would be the **relation** between a subordinate and a senior in an **organization**. It is however quite difficult to imagine absolutely symmetrical **relations**, which would imply an also absolute reciprocal inertia of the **elements**.

According to the cited authors, **asymmetry** involves a **dynamics** tending toward a structural **equilibrium**. In their own words: "Since no **organization** is ever in complete **equilibrium**, the striving toward **equilibrium** is the equivalent of the reduction of **asymmetry** to **order** in **seriality**" (p.49).

However, **dissipative structuration** manifests the opposite **process**: **symmetry-breaking** leading to a higher **level** of **complexity**, generally more **asymmetric**.

Numerous types of **structural** symmetry are possible in two or three dimensions, since different symmetries can result of different rotations in **space**, for instance 90°, 60°, 45° or 30°. The most symmetric figures in 2- and 3-dimensional space are the circle and the sphere.

Crystals present various types of more or less perfect symmetries in three dimensions.

Symmetry is many times *presumed*. H. SABELLI observes: "The so-called postulates of symmetry are so widely accepted in physics that many as yet unobserved **phenomena** have been formulated for reasons of symmetry. However, symmetry breaks down in the most important **parameter**: **time**" (1984, p.356). And: "The consideration of **order** and **structure** is not sufficient. Even more important is that of **time-dependent**, changing orderings and **structurations**. The **process** of ordering is both logically and existentially prior to the static **order** that it generates" (p.357).

This is also the lesson of PRIGOGINE's **far-from-equilibrium thermodynamics**.

3292

SYMMETRY (Antagonistic)²⁾

"A systematic trend toward **adaptability** by the engendering of diverse competitors" (H.G. BURGER, 1967, p.221).

Enhanced **adaptability** is a result of increased **variety**, which can be obtained either by **differentiation** of new types distributed within a **population** or **specialization through competition** of similar **elements** or individuals.

3293

SYMMETRY (Hexagonal)²⁾

The hexagonal symmetry, that appears in many spatial **distributions**, seems to be a result of equalizing reciprocal pressures.

While pressure seems to expand as a **field** radially from a center and generate concentric **circular boundaries** of equal pressure, the reciprocal **limits** of different **fields** tend to adopt regular polygonal layouts, in accordance with the trend to fullest possible occupation of available **space**.

For examples see: "**Hexagonal space filling**".

3294

SYMMETRY (Pentagonal)²⁾

The fivefold symmetry appears in the **forms** of numerous natural systems, as well as in the **clusters** created by **diffusion limited aggregation (DLA)**, which, quoting I. STEWART: "... is baffling because the **rules** for forming the **clusters** do not involve any obvious fivefold symmetry" (1992, p.14).

Fivefold symmetry is also subjacent in the **FIBONACCI series** and the **golden proportion** to which its ratio tends. It seems thus an intrinsic natural property somehow mirrored by abstract number theory.

3295

SYMMETRY-BREAKING^{1) - 2)}

The destruction of symmetry in **space-time**.

J. COLLINS and I. STEWART write: "The simplest **oscillator network** that demonstrates symmetry-breaking consists of just two coupled, identical **oscillators**. Because they are identical, the system behaves in the same way if the **oscillators** are interchanged – that is the symmetry. While the symmetry remains unbroken, the two **oscillators** are in **phase**: they are **synchronized**. But when the symmetry breaks, **group** theory reveals that only one other **pattern** of **behavior** is possible: **antisynchrony**, in which the **oscillators** are half a **cycle** out of **phase** with each other. Not all symmetry need to be lost when symmetries break, however. The **antisynchronous** motion has its own symmetry: the **oscillation pattern** is unchanged if the two **oscillators** are interchanged and their respective **phases** shifted by half a **cycle**" (1994, p.38-9).

Symmetry-breaking is one of the very basic features of nature, possibly since the big-bang itself and is deeply connected with **thermodynamics**.

Classical **thermodynamics** already introduced **time dissymmetry** during the 19th century, even if this was not clearly perceived at the time (f. ex. in BOLTZMANN vain efforts to reconcile **reversibility** with **thermodynamics**). However, the full impact of **thermodynamics** became clear after PRIGOGINE's work on systems undergoing giant **fluctuations** and **dissipative structuration**. He definitively showed that, in the factual world, true **reversibility** is impossible, as a result of **time** symmetry breaking.

As **giant fluctuations** and **dissipative structuration** result of increasing **energy inputs**, it is "... an external **field** which imposes the way the symmetry must be broken". And "Thus the ability to break symmetries corresponds to an adaptive capacity... It is also an advantage to be able to break symmetries all the time, that is to maintain oneself just in the **vicinity** of the **phase transitions**, or in a self-organized **critical state**" (E. BONABEAU, 1993, p. 830-1).

E. JANTSCH states: "Passing from... the **thermodynamic** to the **dissipative structures level**, implies breaking the spatial symmetry between **subject** and **object**, **observer** and **observed**. This general breaking of spatial **isotropy** leads to a **non-equilibrium** world in which "**order through fluctuation**" can become an evolutionary principle" (1975, p.95). In synthesis, symmetry breaking leads to **dissymmetry**, which in turn leads to complementary **organization**.

3296

SYMMORPHOSIS²⁾⁴⁾

"The precise tuning of all structural **elements** to each other and to the overall functional system" (E. WEIBEL, 2000)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This aspect of animal physiology is a yet quite insufficiently explored subject. R. DUDLEY who reviewed WEIBEL's book (2000, p. 557-558) insists on the interest to recognize the need for "compromise between varying demands and intrinsic **constraints** that has yielded present day **patterns** of physiological **adaptation**"

Symmorphosis seems to be to physiology what d'Arcy THOMPSON's research on structural differences in animal's **evolution** has been in anatomy. In both cases internal **constraints** between **structures** and physiological **processes** in animals are emphasized and it can be seen that conditions of **compatibility**, **cohesion** and **efficiency** among parts or **sub-systems** are unavoidable need for any type of **dynamic systems**.

→ Auto-genetic systems precursors; Entropy production (Theorem of minimum); Growth (Allometric); Synchronization; Synergy

3297

SYMPTOM¹⁾

Any **signal** or **event** that indicates some incipient **change** in a system or a systems **process**.

Symptoms are mostly systemic **phenomena**.

Such interpretation is important because symptoms must be perceived and their **perception** and interpretation depends on the nature and quality of the conceptual **frames of reference** of the **observer**. The symptom loses much of its meaning or may even be overlooked if it is seen in an unconnected way, without a good **understanding** of the inner **organization** of the affected system and of its **relations** with its **environment**.

3298

SYNAPSE⁵⁾

The small interval in a **neural network** at which a nervous impulse passes from the axon of an emitting neuron to the dendrite of a receptor **neuron**.

What happens in the synaptic interval (or cleft) is a quite complex **process of transmission**. The electric impulse from the axon is not directly transmitted to the receptor dendrite. It triggers a **sequence** of exchanges based on specific biochemical molecules, from the terminal knob of the axon to the receptor dendrite. After transmission the chemical signal is again transformed into an electrical impulse and the synaptic cleft returns to its potentially receptive state through specific **feedbacks**.

A better understanding can be obtained for instance from J.C. ECCLES's work (1977), J.Z. YOUNG's (1978) or more recently Rita CARTER's book (1978).

→ **Synaptic weights**

3299

SYNAPTIC WEIGHTS^{2) - 5)}

Balancing coefficients applied to the **inputs** of artificial **neurons** in a **network**.

This expression is derived from the biological "**threshold automat**" model of brain **neurons** (W.S. Mac CULLOCH and W. PITTS, 1943). The weighted **inputs** are subsumed and the result triggers the **element** action or inhibits it.

Neural networks "learn" through the progressive determination of the synaptic weights which correspond to repeated **inputs** of the same types. Values of the coefficients become progressively stabilized through **feedbacks** from the **outputs**, which themselves tend to stabilize.

see figure below

→ **Parallel Distributed Processing**

3300

SYNCHRONIC and DIACHRONIC^{1) - 3)}

Superficial exponents of structuralist concepts frequently oppose the **diachronic** aspects of **structures** to their **synchronic** aspects. Some even understand **structure** as a pure **synchronic** concept.

J.L. LE MOIGNE observes on this matter: "(PIAGET concluded that) **structuralism** is in fact a **method**, not a doctrine. He proposed a global approach describing the **object** as a **whole**, functioning and transforming itself (...): "The nature of the subject is to be a functioning

Figure: see entry **SYNAPTIC WEIGHTS**

Modifying Synaptic Weights.

Adapted from G. YAMIAOUI & J. L. AMAT - La Recherche. V. 24, N° 252 - March 1993

center and not the seat of a completed entity" (quote PIAGET, 1968, p.123). May the **object** not be perceived "as a bundle of **transformations**" (Ibid, p.124) operating and evolving only through its own operations?" this constant duality, or more precisely bipolarity of properties, being always simultaneously structuring and structured" (LE MOIGNE, 1990, p.11).

LE MOIGNE also quotes the Swiss linguist F.de SAUSSURE: "synchronic **truth** appears to be the negation of diachronic **truth** and, looking at the matter in a superficial way, one imagines that one must choose; in fact, this is not necessary as one of these **truth** does not excludes the other" (1990a, p.29)

In fact, a **structure** is **diachronic** as well as **synchronic**: each instantaneous **state** of the **structure** is an embodiment of its temporal **totality**.

3301

SYNCHRONICITY¹⁾

The coincidence in **time** of **events** or **patterns**.

The **concept** is somewhat ambiguous.

It could have an absolute theoretic **meaning**: two (or more) **events** are truly synchronic when they occur at the same instant. However, they could very well not appear as synchronic to different **observers**, while **observers** are who decide on synchronicity, *as they observe events*. Referentials are relative.

Furthermore, observed synchronicity is easily spurious. The simultaneous **observation** of many stars by an astronomer does not make their existence synchronous, nor even possibly contemporary of each others.

F. DAVID PEAT uses the concept in a somewhat dubious manner, quoting for example C.J. JUNG, who abundantly used it, speaking of "meaningful coincidence" (1988, p.1). What does however mean "meaningful" and for whom?

3302

SYNCHRONIZATION²⁾

Reciprocal **entrainment** between two or more **oscillators** with, in addition, exact lock-step of **phase**. (Adapted from S. STROGATZ and I. STEWART, 1993).

Synchronization is one of the most basic needs for securing and maintaining **coherence** in systems.

Synchronization corresponds to the emergence of an **attractor** between the various **periodic** movements of distinct **oscillators** that become **coupled**. The **attractor** is normally **cyclical**.

A.T. WINFREE discovered that, in a system comprising many **oscillators**: "... the system's **behavior** depends on the width of the **frequency** distribution. If the spread of **frequencies** is large compared with the **coupling**, the system always lapses into incoherence, just as if it were no coupling at all. As the spread decreases below a critical value, part of the system spontaneously "freezes" into **synchrony**" (STROGATZ & STEWART, 1993, p.73).

These authors add: "Synchronization emerges cooperatively. If a few **oscillators** happen to synchronize, their combined, coherent **signal** rises above the background din, exerting a strong effect on the others" (Ibid).

This is an effect quite comparable to **percolation** in **composite systems** (and possibly the key for explaining how **composite systems** may become more coherent, i.e. **integrated**).

Moreover: "When additional **oscillators** are pulled into the synchronized nucleus, they amplify its **signal**. This **positive feedback** leads to an acceleration outbreak of **synchrony**". However: "Some **oscillators** nonetheless remain unsynchronized because their **frequencies** are too far from the value at which the others have synchronized for the coupling to pull them in" (Ibid, p.74).

According to WINFREE (as quoted by STROGATZ and STEWART): "... mutual synchronization is strikingly analogous to a **phase transition** such as the freezing of water or the spontaneous magnetization of a ferromagnet. The width of the **oscillators' frequency distribution** plays the same role as does temperature and the alignment of **oscillator phases** in **time** is the counterpart of an alignment of molecules or electronic spins in **space**" (Ibid).

This is a significant new link between physics and biology. It confirms the status of synchronization as a **General Systems model** and even is a new example of the wide reach of some **systemic-cybernetic models**.

The role of **time** in the biological synchronization is also to be remarked. (KORZYBSKI's **time-binding**).

→ **Entrainment; Phase locking**

3303

SYNCHRONOUS (Anti-)²⁾

The character of two **phase locked oscillators** when one's minima correspond to the other's maxima.

A good example are the legs of a walking person: When one moves, the other rests on the ground.

3304

SYNCHRONY^{1) - 2)}

The interconnected **behavior** of two or more **oscillators** with similar **periodic rhythm** or **rhythms**.

A.T. WINFREE showed that synchrony may or may not be **stable** (1980).

S. STROGATZ and I. STEWART offer different examples of synchrony: perfect synchrony (identic and simultaneous **frequencies**); anti-synchrony (identic **frequencies**, but in polar opposition); two in synchrony and a third out of **phase**; two in synchrony and a third with a twice as fast **frequency**; etc.

These authors comment: "Synchrony is the most obvious case of a general effect called **phase locking**: many **oscillators** tracing out the same **pattern** but not necessarily in step. When two identical **oscillators** are coupled, there are exactly two possibilities: synchrony, a **phase** difference of zero, and antisynchrony, a **phase** difference of one half" (1993, p.71).

→ **Numbers (Prime)**

3305

SYNCHRONY (Symmetry breaking in)²⁾

Synchrony is not necessarily always symmetric.

S. STROGATZ and I. STEWART explain this: "**Symmetry breaking** governs the ways that coupled **oscillators** can behave. Synchrony is the most symmetrical single **state**, but as the strength of the **coupling** between **oscillators** changes, other **states** may appear. Two **oscillators** can couple in either synchronous or **antisynchronous** fashion,... corresponding roughly to the bipedal locomotion of a kangaroo or a person. Three **oscillators** can couple in four ways: synchrony; each one third of a **cycle** out of **phase** with the others...; two synchronous and one with an unrelated **phase**... or in

the peculiar rhythm of two **oscillators antisynchronous** and the third running twice as fast... This **pattern** is also the gait of a person walking slowly with the aid of a stick" (1993, p.72).

A growing **variety** of combinations can be produced by a growing number of **coupled oscillators**.

3306

SYNCRETISM¹⁾

The tendency to mutual **integration** of different **cultures** or belief systems.

Syncretism is obviously a **systemic phenomenon**. It has not yet however been much researched in systemic ways.

M. MARIYAMA's study of comparative **mindscapes** is an important contribution to the subject (1976, 1979, 1994).

3307

SYNECHISM²⁾³⁾

The tendency to regard everything as continuous.

This neologism was introduced by PEIRCE (see collected papers 1998) and is quoted by R. ROBERTSON (2001, p. 22)(who, by the way, observes "Peirce was always one to coin a new term, which often makes reading him a process of translation) (Ibid.)

Anyhow, the scope of Peirce's studies on **continuity** in **space** and in **time** shows him as a precursor of D. BOHM's "**implicate order**", based on **quanta**; of PRIGOGINE's **emergence** of more complex entities through **dissipative structuration** and even possibly of still more recent physics **models** that tend to consider any structured matter as a provisional "ripple" in the basic **space-time** continuum.

The similarity with SPENCER BROWN's **laws of form** using recursive **distinctions** is also intriguing and probably significant as signaling a **connection** between the concepts of "**whole**" and "**void**". (see J. ENGSTROM, 2001, p.25-66)

→ **Quantum vacuum**

3308

SYNERGETICS^{1) - 2)}

"An **interdisciplinary** field of research that deals with systems composed of many **subsystems**" (H. HAKEN, 1993, p.1015).

In a more colloquial **language**, synergetics investigates "the ways things work together".

H. HAKEN explains: "By their **interactions** with each other, these **subsystems** may produce spatial, temporal or functional **structures** via **self-organization**. Synergetics seeks for general principles underlying these **processes**, where it focusses its attention on those situations where **self-organization** sets in, i.e. where new qualitative features of a **complex system** emerge. Basic concepts ... are **stability** and **instability**, **order parameters**, the **slaving principle**, **critical fluctuations**, for-

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

mation of spatial or temporal **patterns, chaotic states**. The fields these methods have been applied to comprise physics, chemistry, biology, computer sciences, sociology, economy, physiology, and psychology" (ibid).

HAKEN distinguishes three different methods used by synergetics, depending on the kind of tasks:

"a) *The microscopic approach*. In it is assumed that the individual **variables** of the **subsystems** and the **laws** for their temporal **evolution** are known. Then, close to **instability** points, when new **patterns** emerge, the theory shows that the dynamics of the whole system is governed by a few **variables**, the so-called **order parameters**, which enslave the **subsystems**. This approach is also valid in the mesoscopic case, e.g. in fluid motion, where again the basic equations are known though not for the molecules explicitly, but for the volume **elements**.

"b) *The macroscopic approach based on the maximum information (entropy) principle*. In this approach it becomes possible to determine the **distribution function** of a system **far-from-equilibrium** by means of special moments, or the determination of Fokker-Planck equation, starting from specific correlation **functions**.

"c) *The phenomenological approach*. If the microscopic of meso-dynamic **laws** are not known, one may nevertheless try to describe a system by means of adequate macroscopic quantities, namely the **order parameters**" (ibid, p.1016).

The study of processes like **autogenesis, self-catalysis, self-organization** and **auto-poiesis** is central in synergetics.

In a recent paper Elena KNYAZEVA (Russian Academy of Sciences) argues that "Synergetics is a mental scheme or a **heuristic approach** to exploring the complex **behavior** of systems, rather than a universal key to solving concrete scientific problems" (2003, p. 53)

She adds: "Synergetics does not invent speculatively general evolutionary laws, it discovers them and put **boundary conditions** on their application. To use synergetic **models** is likely to get into the inner **mechanisms** of **evolution** and **self organization** of **complexity** in nature" (p. 54)

Synergetics studies are led at the Russian Academy of Sciences within the Keldysh Institute of Applied Mathematics (Prof. S.P. KURDYUMOV) and the Institute of Mathematical Modelling (Prof.A.A. SAMERSKII)

E. Knyazeva signals the following developments in synergetics that take place at the Academy:

1- the investigation of mechanisms of **localization** of **processes** and the formation of **structures** in open **nonlinear media**

2- the idea of discrete spectra of dissipative structures-**attractors** in open nonlinear media

3- investigation of very fast developing processes and their self-strengthening in open nonlinear-media (blow-up **regimes**)

4- studies in the principles of **integration** and construction of complex structures, including the exploration of ways of **co-evolution**

5- the principles of non-linear **management**.

The author also connects PRIGOGINE's works with synergetics, as well as the basic model of **self-organized criticality** (the sandpile model) (ibid)

The transdisciplinary character of synergetics is becoming evermore evident.

3309

SYNERGISTIC SELECTION ²⁾⁴⁾

Positive selection produced through a trend towards **cooperation** among **clustering elements**.

This notion has been introduced by J. MAYNARD SMITH in his paper on "The Evolution of social behavior" (1982, p. 28-44) and developed by him and E. SZATHMARY in subsequent papers.

It is to be noted that the concept of "advantage through **altruism**"-a **value**-laden concept - has been progressively abandoned by MAYNARD SMITH and others and replaced by the more neutral (and measurable) one of **cooperation**.

It could even be argued that cooperation is probably in itself a result of a primarily accidental **association** which produced a common **reinforcement of fitness** in some specific **environment** and/or circumstance.

P. CORNING produced a handy **synthesis** on the subject (1998b., p. 25-26)

→ **Kin Selection; Symbiogenesis**

3310

SYNERGY PARADIGM ¹⁾²⁾³⁾

The use of the synergy concept to explore all kinds of **relationships**, as proposed by P. CORNING (1998b, p. 27-28)

CORNING writes: "What are the implications of a "synergy paradigm?" First, it could serve as a lingua franca for the cooperative/emergent/interactional **effects** that are observed and studied by various disciplines. By removing a **language** barrier, the term could facilitate **cross-disciplinary communication** and **understanding**.

" Second, by directing our attention to **context-specific "historical" relationships** and **interactions**, rather than "**mechanisms**" or **reductionist "laws"**, the synergy paradigm encourages a multi-leveled, **multi-disciplinary** research and theory that is free from the intellectual shackles of 19th century Newtonian physics. Furthermore, the synergy **paradigm** draws our attention to the functional aspect of cooperative **effects**. As noted earlier, concepts with broad applicability to many different kinds

of **phenomena** may play an important theoretical role in the sciences. The synergy concept provides a **framework** for integrating the research in various disciplines that may be relevant for understanding the broader causal **role** of **cooperative phenomena** in nature and **evolution**. To borrow the "pre-owned" parable of the blind men and the elephant, if we are ultimately to make sense of the **whole**, we will need to pool our discoveries about both the **parts** and the whole.

"All scientific concepts are inescapably Pro-custean and selective, highlighting certain aspects of the phenomenal world to the exclusion of others. None can be all things to all scientists. The ultimate test is fruitfulness. By the standard, the concept of synergy would seem to hold promise. Among other things, it offers a theoretical **framework** which, like the concept of natural **selection**, can provide a focus for explaining a major aspect of the evolutionary **process**, namely, the evolution of organized **complexity**. Indeed, an invigorated science of synergy would shine a spotlight on a fundamental property of the **phenomenal** world. Equally important, because it is pan-disciplinary (and egalitarian) in its **methodological** implications, the concept of synergy could provide a useful bridge between various specialized disciplines. If synergy can provide functional advantages elsewhere in the phenomenal world, why not also within the scientific enterprise itself". (ibid)

3311

SYNERGY

"The action of two or more substances, **organs** or **organisms** to achieve an effect of which each is individually incapable" (The American Heritage Dictionary).

Another definition, by Ch. HAMPDEN-TURNER, as quoted by N.A. COULTER Jr. reads: "Synergy is the fusion between different aims and **resources** to create *more* between the interacting parties than they had prior to the **interactions**" (1979, p.26).

COULTER also gives his own definition: "... any property of a system that promotes two or more **functions, processes, goals**, etc., while impeding none" (ibid).

COULTER observes that synergic power transcends **hierarchic** directive power, specially in **organizations** where it fosters: "...the ability to engage others in joint efforts to increase the satisfaction of all" (ibid., p.27).

According to BECKMINSTER FULLER, (as quoted by O. JOHANSEN BERTOGLIO): "An **object** shows synergy when, examining one of various of its **parts** (or even each and everyone of them) separately, it is impossible to explain or predict the **whole's behavior**" (1985).

In this case, we call it a system, in view of the new global **behavior** resulting from the **interactions** among the **parts** or **components**.

L. KOHOUT and B. GAINES state: "The synergies increase the speed of reaction of the **organism** as well as decrease demands on **information**-processing capacity during the **synthesis** of a particular action or movement."

They extend soon this view to computing **processes**, where, according to them synergies appear as: "... **subroutines**, ready as **whole** units to be triggered off in an appropriate **situation**" (1976, p.17).

Curiously however, synergy implies at times that **parts**, in order to become synergic, must partly relinquish some aspects of their own **behavioral patterns**.

In the recent years, (1983 to day) P. CORNING has deepened the study of synergy as a fundamental systemic **phenomenon** of a typically **transdisciplinary** character. He emphasized its very general nature as "the subset of all imaginable **interactions** that have combined functional **effects** (positive or negative) and added: "Synergistic **causation** is **configurational**: synergistic **effects** are always co-determined" (1998b, p.8-10).

And finally: "Synergy is real. Its effects are measurable and quantifiable: e.g. economies of

scale, increased **efficiency**, reduced **costs**, higher **yields**, lower mortality **rates**, a larger number of viable offsprings, etc... More subtle measuring rods include enhanced **stability** properties, greater **stress tolerance**, increased fidelity in **reproduction**, the melding of functional **complementarities** to achieve new properties, and so forth" (Ibid, p.12).

CORNING advocates for a "Science of **Relationships**", whose main research tool would be a "**synergy paradigm**" (see hereafter).

CORNING produced the following table of **synergistic effects** in a selection of scientific disciplines (Ibid, p.8):

see table below

For complementary information, see reference 1998b.

3312

SYNTACTIC NOISE³⁾

"Any **structural** difference between a **message** sent and the **message** received" (R.L. ACKOFF & F.E. EMERY, 1972, p.182).

These authors, who introduce the notion, make a curious comment: "Even if a **message** is not changed structurally, it may not be received (that is, interpreted or decoded) as it was sent. What is intended as a compliment by A may be interpreted as an insult by B: "You look so much younger than you are" (Ibid).

Is this not stretching the notion too much?

3313

SYNTACTICAL REDUNDANCY²⁾ - 3)

The fraction of a **message** that is unnecessary if no **noise** must be overcome.

Syntactical redundancy is related to the **knowledge** the **receiver** has of the **code** used. For example, in the word "quite" the letter "u" could be generally omitted, because it is well known by English-speaking persons that the letter "q" is always followed by the letter "u".

3314

SYNTACTICS¹⁾ - 3)

The branch of **semiotics** that deals with the properties of **signs** and **symbols** and with their formal **relations**.

Correct syntactics is the condition of a transparent use of any **language**. It implies proper coordination between all the **rules** characteristic of the **language**, and thus its global **structure**.

GERNERT (2000 a, p. 155) comments: "Syntactic **information** is the alteration produced by incoming **signals** in the heads of telecommunication engineers who are waiting at the end of the **channel** and value the finished **transmission** under the aspects of their profession, e.g. **channel capacity**, **efficiency**, or **reliability**" (p. 160)

This seems to be basically a technical viewpoint, bearing upon **communication** under SHANNON's original **meaning**.

GERNERT himself made the point (his 2000 b) paper), quoted in the entry "**Information theory**")

Even so, syntactics seems to include two **codings**:

1) an electro-magnetic one through which a specific electro-magnetic signal corresponds to a specific **sign**

2) a sign (for example, a spoken word) corresponding to a shared **code** between a sender and a receiver, let us say for example "pencil" in a telephone conversation (What is the meaning of "Bleistift" for someone who does not know german?)

3315

SYNTAX¹⁾ - 3)

"The rules by which **symbols** can be concatenated to form legitime strings" (H.von FOERSTER, 1981, p.217)

Table: see entry SYNERGY

Discipline	Representative Examples	Associated Terminology
Quantum physics	Quantum Coherence	Holism , ordering
Physics	Chaotic Phenomena	Emergence , interactions , attractors , order
	Self-organized critically	Interactions , holism
	Phase transitions braking	Cooperative effects , symmetry
Thermodynamics	Dissipative structures	Order/disorder low entropy , negative entropy , order , emergence
Biophysics	Hypercycles	Cooperation , interactions , Coordination , order , emergence
Chemistry	Molecular macrostructures	Symmetry , collective stability , order
Biochemistry	Supramolecules	Interaction functional integration Coordination
Molecular Biology DNA	DNA	Complementarity , epistasis , heterosis
Developmental Biology	Homeobox Homeotic genes	Organization , cooperation , coordination
Neurobiology	Neuronal transmission	Cooperativity, thresholds effects , emergence
Ecology and parasitism Behavioral Biology	Coevolution	Interactions , mutualism
	Symbiosis	Mutualism , cooperation
	Sociobiology	Mutualism reciprocal altruism , emergence , cooperation , division of Labor

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Such **rules** form an interconnected and interactive **set** and **structures** any type of **language** or **signs** system.

However, as argued by J. SEARLE, "no amount of syntax alone (i.e. **symbol** shuffling) can ever give rise to **semantics**" (Quoted by J. CASTI, who adds the comment that the classical **symbol** shuffling computer "can have no understanding of the *meaning* of the **symbols** it manipulates" (1994, p.163).

von FOERSTER observes: "... **semantics**, i.e., the **rules** that give **meaning** to those strings, was long a dirty word. This is not so any longer after it has been recognized that syntactic ambiguities are disambiguated in the **semantic domain**" (Ibid).

Semantics is thus at the **metalevel of validation** for syntactic constructions. This should be obvious, as it is perfectly possible to construct non-sensical strings of **symbols** without any violation of syntactic **rules** ("The dog burns the silken palmtree"), or even that such strings become meaningful only if and when the **receiver** knows the **semantic frame** in which they make sense. ("Mtoto alivunjika sahani"... a perfectly significant sentence in Kiswahili).

3316

SYNTEGRITY

The combination of **synergy** and **integrity** resulting from all the possible **interactions** of a number of participants.

The **concept** of **syntegrity** has been introduced by S. BEER (1994). It is derived from BUCKMINSTER FULLER's **tensegrity** and BEER applies it to the exploration of some topics by a group of 30 people (See "Team Syntegrity")

The basic **model** is the icosahedron, with its external and internal **connections** (1994, p.284-5) whose graphical **representation** shows all the possible **interrelations** among the participants.

3317

SYNTHESIS (Systemic methodologies of) ¹⁾

The achievement of a satisfying global vision of a system involves a difficult methodological problem: **Synthesis**. In spite of its importance it did not worry too many systemists up till now, except J.L. LE MOIGNE ("Theorie du système général", 1990a) and R. RODRIGUEZ DELGADO (1993b) This last author distinguishes the following different ways toward synthesis:

"- **Structural synthesis**: Once **structures** have been analyzed and well known they should allow for a global and renewed **representation** of the system.

"- **Functional synthesis**: the same **structures** may lead to various functional **distributions**, which should be optimized. **Synthesis** and **generalization methods** allow for the global study of **functions** and the shaping of functional **models** which will permit to select some convenient ones.

"- **Relational synthesis**: synthesis and generalization **methods** also may be used for the shaping of **models** of the systems internal and external **relations** and of criteria allowing for the best adapted **choices** respect to the problem or the **situation** as it is.

"- **Historical synthesis** : historical synthesis studies allow for a global view of the system **development** in **time** and for predictions which would not be possible by other techniques.

"- **Interdisciplinary synthesis**: which takes place when two or more disciplines formerly isolated become united as for example: Physico-Chemistry, Biochemistry, Sociocybernetics, or **Ecology**.

"- **Prospective synthesis**: by use of **feed-forward techniques** it becomes possible to better **short-term predictability** and to establish probable **medium** and **long term scenarios**.

"Synthesis techniques vary widely according to the **class** of systems to which they are applied" (1993b, p.293-4).

One may also think that the various synthesis **methodologies** are in every case depending on specific systemic concepts.

For example:

- Structural and functional synthesis should be grounded on a common **taxonomy of subsystems** (MILLER, 1978) and on the concept of **synchronic-diachronic structure**.
- Relational synthesis should use **interconnections graphs** and anew the **taxonomy of subsystems**, as well as the concept of **interface**.
- Historical synthesis does not seem yet to have found its own systemic and cybernetical **models**. The concept of **limit cycle** and those of **morphogenesis**, **steady state** and **ageing** would probably be useful.
- Interdisciplinary synthesis involves finding new **objects** for research which could be modeled as **complex systems** as for example cyclical **catalytic** reactions, synaptic **connections** in neural **networks**, **autopoietic organizations** or biotopes.
- **Prospective** synthesis depends upon skilled use of the concepts of **bifurcation**, **catastrophe**, and combined **cyclical rhythms**, among others.

3318

SYNTONY ^{1) - 2) - 4)}

The collective **behavior** resulting of reciprocal **entrainment**.

Syntony can be considered as a weaker form of **synchronization**. It is produced through the reciprocal **perception** by the **elements** of their more or less regular **behavior**. It is a **phenomenon** of **resonance**.

Syntony is present in many biological and physiological **phenomena**, as well as in social ones. The **emergence of paradigms**, or in German the "Zeitgeist" or the "Gleichschaltung" are cases of cultural syntony, traduced in shared beliefs.

In **Evolutionary Learning communities (ELC)**, a more open understanding of syntony emerges. K. BAUSCH describes it as follows:

"Conscious intention aligned with evolutionary **purpose**; more loosely, the embodiment and manifestation of conscious **evolution**; a purposeful creative aligning and tying with the evolutionary **flows** of one's **milieu**" (Glossary, Pers. comm., 2002)

3319

SYNTONY QUEST ¹⁾⁴⁾

Alex and Kathia LASZLO have adapted the **concept** of syntony to **human systems**. Syntony Quest is about seeking "to catalyse **learning processes** that empower individuals and **groups** to develop the competencies necessary for the co-creation of **sustainable**, evolutionary futures"

Essentially, they propose:

- transformative **learning**
- the **design** of self-directed learning processes
- the acquisition of evolutionary **competence**
- the conscious creation of **sustainability**

They base these proposals on the following areas of **knowledge**:

- **evolutionary systems theory**
- social systems **design methodology**
- transformative learning philosophy

They consider that "these approaches lead to the mastery of the **knowledge**, abilities, **attitudes**, and **values** required for co-evolutionary **action**, and thereby, for the pursuit of sustainable modes of being.

Syntony Quest is an **organization** (based in San Francisco, e-mail: **Syntony.Quest@usa.net**) "dedicated to the **development** of evolutionary **competence**" that seeks "to foster the **emergence** of **evolutionary learning communities** (ELCs) and communities of ELCs, i.e. evolutionary learning **ecosystems**"

Such ecosystems obviously included human active participation. The ELC concept has been mainly developpe by A. Laszlo himself (partly during **Fuschl Conversations**)

3320

SYNTROPY ²⁾

"The process of **negentropy** importation" (K. BAUSCH, glossary, Pers. comm., 2002)

BAUSCH adds: "a syntropic system is a **dissipative structure**" (ibid)

So called negentropy can be imported into the system as **energy inputs** or as already organized **matter** (food for ex. or pure iron, refined from iron ore)

Dissipative structuration is more readily associated with inputs of energy that is used by the system to maintain existing **structures**, or create new ones in case of excess of energy inputs.

→ **Emergence; Energy Entropy; Entropy production (Theorem of minimum); System (far from equilibrium)**

3321

SYSTEEM GROEP NEDERLAND ¹⁾

or Dutch Systems Group.

The Systeem Groep Nederland is one of the oldest Systems Society in existence. It "supports and promotes professional interests and ideas on the subject and serves as a base for the exchange and distribution of the results of research".

The S.G.N. publishes the Journal "Systemica" since 1980. It also organizes international conferences on generally quite original thematics related to cybernetics and systemics as for example: "Knowledge (dis)emergence", "Mutual uses of Cybernetics and Science", or "Problems of (Im)Possible Worlds".

The S.G.N. has been one of the three original founders of the **International Federation for Systems Research** and took charge for some quite critical years of the publication of "Systems Research", the Federation's Journal.

3322

SYSTEM ¹⁾

Very numerous definitions have been given of the word and the concept even if limited to G.S. Theory and Cybernetics, the differences between these definitions are striking. However, comparisons do not destroy the notion. On the contrary, many interesting shades appear.

Accordingly, we give hereafter many definitions, obtained from authors of different countries and specializations. As much as possible, they are supported by comments of the authors themselves. In some cases a critical **evaluation** or comment has been added.

The general idea is to extensively explore the multiple aspects of the notion in a non-contradictory way.

To put things into perspective here is G. WEINBERG's one: "The system is a point of view". And, similarly, for G. PASK it is a "universe of discourse" (predefined by a **reference frame**) (1961, p.22-3).

So "System" corresponds to a man-created general conceptual **model** for coherent, complex and more or less identifiable and permanently observed real world entities.

All definitions are more or less complementary. Some are more embracing than others and others more specific. All in all, this is one of the most evident case of **polysemy in language** and it would not be satisfactory to reject any off-hand without a careful scrutiny.

It should however be noted that no "point of view" and no "**universe** of discourse" on systems could exist without the simultaneous existence of something on which these subtle arts can be practised and which is generally called "**concrete system**", or perhaps more imprudently "real" system.

As a result, the most simple and synthetical definitions open the way to careless generalizations and simplifications.

The most elaborated can be limitative, for example, be valid only for **living systems**.

Furthermore there are *various* degrees of systemic **organization**, from the least **integrated** (composite or distributed systems) to the most differentiated and **integrated** ones.

Shortly, there is no perfect definition... and, again, many possible ones according to the "point of view".

Accordingly, we will thus give a number of them, first general, next more specific, in every case with the needed comments (from the authors or from this compiler, according to necessity). Most definitions are from genuine systemists or cyberneticians, and some more from other scientists or philosophers, because they seemed relevant.

In conclusion, a critical **synthesis** will be proposed, even as the conclusions are by no means to be taken as definitive.

Definitions

- "A system is a **set of elements** dynamically **interacting** and **organized** in relation to a **goal**" (J.de ROSNAY, 1990, p.93).

J.de ROSNAY comment is as follows: "The introduction of finality (the **goal** of the system) in this definition may seem surprising. Understandably, the **finality** of a **machine** has been defined and specified by man, but what dare we say about the **finality** of a system like a **cell**? The cell's "**goal**" is in no way mysterious. It implies no project. It is registered *a posteriori*: to maintain its **structure** and to divide itself. The same can be said about the **ecosystem**. Its **finality** – again, not project – is to maintain its **equilibria** and to allow life's development. Nobody did established atmosphere's content of oxygen, nor the earth's average temperature, nor the composition of oceans. Nevertheless, they maintain themselves within very narrow **limits**.

"This definition steps back from another with a certain **structuralist** overtone, for which a system is a **closed structure**. Such **structure** cannot evolve, but undergoes **collapses** due to some internal **desequilibrium**" (ibid).

"A set of **parts** with a common destiny, which maintain their **interrelations**, even when placed in a different **environment**" (F. BON-SACK, 1990, p.67).

The author comments: "In a system, there is first an object: a certain **connexity** in **space**, a conservation of internal **relations** at the **time** of a displacement entailing a **change** in the relations with the **environment**..."

"But there is more to it.

"There exists a **functional** unity. This means, a **whole** apt to perform some tasks and which needs the **functional** integrity of all of its **parts** in order to maintain that capacity..."

"...a car (for example) performs correctly its **function** – which is to guarantee quick, safe and comfortable travelling at whatever hour and practically any weather conditions – only if all **parts** correctly perform their respective **function**" (p.67).

"A **set** of interrelated **elements**" (BERTALANFFY, 1956 – ACKOFF, 1972).

This sweeping and embracing general definition is thus explained by R.L. ACKOFF: "... a system is an **entity** which is composed of at least two **elements** and a relation that holds between each of its **elements** and at least one other **element** in the **set**. Each of a system's **elements** is connected to every other **element**, directly or indirectly. Furthermore, no **subset** of elements is unrelated to any other **subset**" (ibid).

This definition does not allow a clear **distinction** between logical or **formal systems**, for example, and dynamic **concrete systems**. Nor is the role of the **observer** in any way expressed.

"... any **set** of **variables** that (the **observer** or experimenter) selects from those available on the real "**machine**" (W.R. ASHBY, 1960, p.16).

One very important feature of this definition is the emphasis upon the role of the **observer** or experimenter, who is supposed to "select" the **variables**, and whose intervention implies clearly that, in ASHBY's opinion, any system is a mere **constructed model**. Of course, some **criteria** would be needed, in order to avoid radical arbitrariness in the **process** of selection. A **criterion** should be, for instance, *coherence*, in relation to some general types of **interconnections** present in all **systemic-cybernetic models**. One should also note that ASHBY postulates the existence of the real "**machine**", an **object** "out there", which may very well be differently modeled by different **observers**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Finally, one could regret the use of the word "**machine**", a practice of the first cyberneticians which has been sharply criticized for its **mechanicists** undertones.

"A grouping of interrelated **elements** possessing a **boundary** and functional unity" (Ch. DECHERT, 1968, p.119).

DECHERT writes: "Each of the **elements** of a system is related, directly or indirectly, to all other **elements** so that a **change** in any **element**, to a greater or lesser degree changes the entire system. A system is distinguished from an **aggregate** (or **congeries**) by the inter-relatedness of its **elements**" (Ibid).

In this sense, a system is basically a **network**.

"A system is an **organization** comprising man and **machine components** b) engaged in coordinated **goal-directed activity**, c) linked by **information channels**, and d) influenced by an external **environment**." (D. HOWLAND, 1963, p.227).

This definition is only adequate for **human systems**, which, furthermore do not necessary include **machines** and whose activities are not always, at least consciously, **goal-directed**.

D. Mc NEIL deplors that: "The word **system** became cheapened by its identification with particular technologies such as computers or with particular **methods** such as "**systems analysis**" (1993 a).

He tries, in a recent and intricate definition, to include the many different aspects of systemic **organization**: "A system is a **dynamic**, organized, delimited, **open**, persistent, **composite whole**. It is **voluntary**, comprised of at least one **loop** and at least one **link** which manifest the aspects of **content**, **form**, **function**, and **control**, together with **timing** and **scaling** factors, relative to an **environment** and relevant to a percipient" (1993a). ("Percipient" stays here for "**observer**", as considered in this encyclopedia).

M. BUNGE gives a very synthetic definition which implies many specific features of systems, save their **relationships** with their **environment** (including how an "**object**" becomes defined): "A system is a complex **object** every part of which is related to some other **component** of the same **object**" (1993, p.211).

However Mc NEIL's definition reflects better the multi-facetic character of the "system"... and the need to ponder each and every characteristic stated in it.

There are numerous more specific definitions of peculiar **classes** of systems, most of which are reproduced – and commented, in view that some seem debatable – hereafter.

To conclude, systems are most generally characterized by their complexity, their **coherence** and relative permanence, and their tendency to seek their own **survival**. These general conditions dominate the whole concept.

3323

SYSTEM (Abstract) ¹⁾ – 2)

A system "all whose **elements** are **concepts**" (R.L. ACKOFF, 1972)

M. BUNGE calls this type of systems "conceptual systems" (1993, p. 211).

ACKOFF comments: "**Languages**, philosophical systems, and number systems are examples. **Numbers** are concepts but the **symbols** that represent them, **numerals**, are physical things... The use of different numerals to represent the same numbers does not change the nature of the system.

"In an abstract system the **elements** are created by defining and the **relationship** between them are created by assumptions (e.g. axioms and postulates) Such systems, therefore, are the subject of study of the so-called formal sciences" (Ibid).

G. KLIR states: "The **isomorphic transformation** from an interpreted system into the corresponding **general system**, which may be called an **abstraction**, is always possible. The inverse **transformation**, which may be called an **interpretation**, is not guaranteed and must be properly justified in each case. Indeed, relations among things based upon **distinctions** made in the real world cannot be arbitrary, but must reflect genuine **constraints** of the real world, as represented in our world of experiences. Hence, each interpreted system determines uniquely its representative **general systems**, by the **isomorphic transformation**, but not the other way around" (1991, p.17).

D. Mc NEIL observes: "... while a system may be represented by static **symbols**, e.g. in a "system" of musical notation, the formalism is only a **representation** of the **structure** of the system and that the system-ness itself is in the **dynamic** application of its **structure**" (1993 b). This is the difference between the score of a symphony and the symphony itself, when performed.

3324

SYSTEM (Adaptive) ¹⁾

Any system able to shift from one internal **state** to another as a **response** to **variations** in its **environment**.

It would be very difficult to conceive a **living** or a **social system** that should not be adaptive, at least respect to a **variety** of **changes** relevant to its **survival**.

R.L. ACKOFF writes: "A system is adaptive if, when there is a **change** in its **environmental** and/or internal **state** which reduces its **efficiency** in pursuing one or more of its **goals** which define its **function(s)**, it reacts or responds by changing its own **state** and/or that of its **environment** so as to increase its **efficiency** with respect to that **goal** or **goals**" (1972).

According to W. BUCKLEY, an adaptive system must be able to perceive **variety** and **constraints** in its **environment**, and to adjust its internal **organization** accordingly (1974).

It must necessarily have sufficient internal **variety** in order to shift from one adapted **state** to another, when needed. Furthermore, it must possess an **array** of **positive** and **negative parameters** defined **feedbacks**, that will allow it to respond to a definite **range** of **disturbances**.

Living systems in general, are more or less adaptive: Among them animal societies and **populations**; human individuals and **socio-cultural systems**.

An interesting bibliography on adaptive systems is given by G. KLIR (1991, p.161).

J. HOLLAND developed a generalized and formalized model of the adaptive system (1992, p.20;24;28)

3325

SYSTEM (Allopoietic) ¹⁾

Any systems "whose **organization** is such that it does not produce the **components** and **processes** which realize them as unities" (F.G. VAR-ELA; H.R. MATURANA & R. URIBE, 1991, p.561).

Man-constructed systems are allopoietic (at least until now).

The authors explain: "The actual realization of these systems, therefore, is determined by **processes** which do not enter in their **organization**".

Furthermore: "Allopoietic systems are by constitution non-**autonomous** insofar as their realization and permanence as unities are not related to their **operation**" (Ibid).

Such systems must be **started**. However, once functioning, and the existence of their allopoietic conditions guaranteed, they seem to possess at least some degree of **autonomy**, specially if they are equipped with internal **regulators**.

→ **Allopoiesis**

3326

SYSTEM (Almost homogenous)

→ **System (Composite)**

3327

SYSTEM (Almost isolated) ¹⁾

Any system which presents the two following characteristics:

1) It is influenced by the outside world, but only through certain defined **processes**, called **inputs**;

2) it exerts an influence on the external world, but only through certain defined **processes** called **outputs** (adapted from H. GRE-NIEWSKI, 1989).

This definition, by GRENIEWSKI and quoted by J.L.LE MOIGNE is reproduced here merely for information. An "almost **"isolated system"** is clearly a "somewhat open" one (as appears from the definition itself) and as such, open or closed in **space** and **time** for specific **inputs** and **outputs**. Thus, while the described characteristic are in effect very general, it would be better to avoid GRENIEWSKI's terminology in this case.

3328

SYSTEM and Environment ¹⁾

1. Any system appears as a discernable entity within its surroundings. This **entity** is endowed with a defined **identity** and a relative permanence.
2. To any system corresponds a significant environment, which is that **part** of the **universe** with which the system has occasional or frequent and characteristic exchanges.
3. The system possesses a **membrane** or **boundary**, permeable in a selective way, composed of **elements** that are able to interact with certain types of **elements** in the environment and also with some specific internal **elements**. This means that the **boundary** is an **interface**.
4. The system obtains from its environment whatever **inputs** it needs for its construction and **maintenance**.
5. The system devolves to its environment the specific products of its activity, transformed or degraded **energy**, re-elaborated **information**, but also **wastes** and **noise**.
6. The system and its environment, through their **interactions**, undergo reciprocal **transformations**.
7. When the system finally disappears, its **elements** recover their **independence** and scatter within the environment or become incorporated in other systems. However, quite frequently some trace or record of the system remains for a more or less long period. (See **"Aura"**).

3329

SYSTEM (Anticipatory) ^{1) - 4)}

A "system that possesses on-going capabilities of building relevant systems **models** of its **environment** and is able to use these **models** for making **decisions** and **actions** that optimize specific **goals**" (Adapted from G. KLIR, 1991, p.190).

Thus: "This means that an on-going systems **modeling** of relevant aspects of the **environment** will be an essential feature of the **decision-making infrastructure** of **organizations**. This implies that expertise in systems science will be in increasing demand by **organizations** in the **information society**" (Ibid).

R. ROSEN observes that "the essence of anticipatory **behavior**... involves the **concept** of **feedforward**, rather than **feedback**". Indeed: "the essence of **feedback control** is that it is *error-actuated*; in other words the **stimulus** to corrective **action** is the discrepancy between the system's actual present **state** and the **state** the system should be in. Stated otherwise, a **feedback control** system must already be departing from its nominal **behavior** before **control** begins to be exercised".

As to the **feedforward** system, its basic condition is: "that present **change** of **state** is determined by an anticipated future **state**, computed in accordance with some **internal model** of the world" (1979, p.183).

This is different of, but consonant with the CONANT-ASHBY idea that "Every good **regulator** of a system must be a **model** of that system": Such a **model** is needed for the system to be able to make more or less reliable **predictions** about its own future when confronted with external (or internal) **disturbances**. It is of course necessarily based on registered past experiences and their outcomes. There is thus no **time paradox** in the concept of **anticipatory behavior**.

3330

SYSTEM (Appreciative)

→ Appreciative System

3331

SYSTEM (Anticipatory)

→ Anticipatory system

3332

SYSTEM (Appreciative) ²⁾

The outside system as it is interpreted by the **observers** through mental **images** according to the **"Weltanschauung"** (worldview) of these observers.

According to G. VICKERS the appreciative systems are cut starting from our expectations and evaluated through our **standards** and **criteria**

→ **Model; Modeller; Modelization; Objectivity; Observer; World models**

3333

SYSTEM as a NETWORK (The) ^{1) - 2)}

According to CH. DECHERT: "Natural systems such as **communities** or **ecological** systems may perhaps be reduced to the resultant of probabilistic **interaction** on the basis of the **behavioral programs** inherent in each **component**" (1968, p. 119).

It would seem that we need to bridge the gap between individual **behavior** and global one by something more than probabilistic **interactions**. At least, these last would have to be somehow stabilized through **rules** of inter-

action. Such **rules** may be intrinsic because the **components** characteristics allow for some **interrelations** and exclude others. The thus defined **constraints** establish the future **autopoietic** nature of the system (see for example von FOERSTER **magnets experiment**).

In the same vein, **cellular automata** are constructed from standard **elements** evolving within a characterized **space**, through defined **rules**.

DECHERT observes: "In artifactual systems, the principle of **integration** is either external, or insofar as such systems are **self-regulating** or **self-organizing**, internal and localized" (Ibid).

A system self-generated as a **network** should be **first self-organizing** and later on **self-regulating**: i.e. it constructs its own internal **determinism**, by progressive reciprocal **emergence** of self-generated **constraints**.

3334

SYSTEM (Autonomous) ¹⁾

"A system whose **action** results of its own impulses, which selects its **goals** and the means to pursue them according to its **knowledge** of the **laws** of the world and its present **perception**" (F. BONSACK, 1990, p.118).

There are various **understandings** of what autonomy means; for a general survey, see: **Autonomy**.

F. BONSACK adds: "The source of **actions** is not however immune to any **feedback** from the world,... but these **inputs** should not be considered as the source of **action**: they only modulate the internal source" (Ibid.).

This is the basic **meaning** of the concept of **autopoiesis**.

R. ROSEN states: "It is absolutely essential... that the **time-dependent inputs**, or forcings, do not change the autonomous **dynamics** in any way. it must neither create nor violate the system **constraints**; more generally, it must not change any of the **parameters** which govern both transient and **asymptotic behaviors** in the autonomous system... This restriction is not often mentioned explicitly, but it is absolutely basic. Unless we impose it, the very **identity** of the system will depend on the **environment** with which it is interacting, i.e. the **identity** of the system *in vacuo* will be different from what it is in a specific **context** which is forcing it, that **identity** has become, in a sense, **context-dependent**" (1993, p.21).

3335

SYSTEM (Autopoietic)

→ Autopoietic system

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3336

SYSTEM (Behavior)^{1) - 2)}

"A *behavior system* is defined by a **time**-invariant relation among selected present, past, or future **states** of the **variables** in the experimental **frame**" (G. KLIR, 1988, p.151).

KLIR comments: "... The **states** are selected by a **mask** through which we observe given **activity** and take samples corresponding to different **time** instants" (1988, p.151).

This implies that, for some **purpose**, we focus our attention onto some type(s) of behavior, possibly or even probably ignoring others.

3337

SYSTEM (Chaotic)

→ Chaotic System

3338

SYSTEM (Closed)²⁾

A system able to absorb and emit **energy** and **information**, but not **matter**.

This definition is generally accepted.

Notwithstanding, the concept of closed system is one of the most semantically dubious in **systemics**.

To begin with, it should clearly be distinguished from the *isolated system* concept, with which it has been sometimes confused. Indeed, the **isolated system** does not absorb or emit anything... and, as a result, cannot be perceived by any **observer**.

It has been also been written by some authors that the closed system exchanges only **energy** with its **environment**, excluding **matter** and **information**. It is quite difficult to imagine a *concrete system* that would offer such a curious characteristic.

Organizationally (or **operationally**) closed systems are also frequently considered closed in this sense, being then defined as a **set of relations** between **components**, such that states **transitions** of the system are **state determined** (H. MATURANA, 1975). However, **concrete systems** that maintain their internal **organization** are able to do that even when they exchange **matter** and, or **information** with their **environment**. Only that some exchanges are admissible and others are not. Obviously "**closure**" does not mean insulation or isolation.

It could be argued that any satisfactory **model** of a **concrete system** must necessarily and simultaneously be open *and* closed, according to the functional requirements of the system. Thus we should speak only about closed (or open) systems specifying the **inputs** and **outputs** they admit or not, as well of the precise moments these are admitted or rejected.

N. GEORGESCU ROEGEN formulates the following basic law: "No closed system can perform mechanical work at a constant rate indefinitely" (1982, p.318). He notes that this **law**

"... is the twin of the **second law of thermodynamics**, which prohibits the endless derivation of mechanical work at a constant **rate** from a finite amount of free **energy**" (Ibid, p.321).

Another problem with the closed system **model** has been emphasized by G. BROEKSTRA (after G. SAGE): "The closed system **metaphor** was that of the **organization** as a **machine** or clockwork" (1992, p.1025). The presence of this **metaphor** in the minds of many business executives has undoubtedly provoked the demise of numerous enterprises. It has also been instrumental to the awful bureaucratization of many **organizations** at the administrative and governmental level. Indeed, when the clockwork is constructed, it is not supposed to be modified outside of its own basic **rules** and it becomes too perfectly "**autopoietic**", losing any adaptive capacity".

As noted by T. BAUMGARTNER et al, "... in general, the assumptions (or theory) underlying closed systems **models** and **methods** contradict the assumptions required (in practice) in a research **situation** involving **open systems**. Rarely, even under experimental conditions, do social scientists *achieve* the degree of **closure** (or **control**) which closed system **models** and **methods require**" (1976, p.39).

There is, furthermore, a **time frame** problem: "Indeed, social science **data** and analyses are often based on a **time span** of **observations** so short that the "open" nature of the system is not detectable, and **relationships** between and among **variables** appear stable" (Ibid).

And this is not only true in human systems, but also in **complex systems** in general.

3339

SYSTEM (Co-)^{1) - 2) - 4)}

Any system whose **activity** is closely coupled to the **activity** of the system under consideration.

In living beings, co-systemic **activity** may respond to **commensalism**, **mutualism**, **symbiosis** or **parasitism**.

The co-system differs from the **subsystem** as it maintains a clearly distinct **identity**.

By analogy, the concept can be extended to **human systems**: for example in economy, an enterprise is connected with many co-systems, as f. ex. suppliers, clients, labor unions, governmental offices, etc...

3340

SYSTEM (Colonial)^{1) - 2) - 4)}

A system that expands by creating new systems of its own kind in its **environment**.

In this sense the conservation of genetic **identity**, or in **human systems**, **language** and cultural **values** is paramount. The maintenance of a strong bond with the original system is also essential.

Many plants are colonial. One of the most interesting case is that of some originally individual poplar trees, which may finally occupy quite a wide area, through offshoots from far-reaching roots. Bracken (in England) is another example. The banyan tree is still another.

Animals do not seem to evolve in colonial systems, save some invertebrates as for example hydras.

In **human systems**, multinational enterprises, religious **organizations**, or the former colonial empires are examples of colonial systems.

3341

SYSTEM (Complex)^{1) - 2)}

"A system made up of a large number of **parts** that **interact** in a nonsimple way" (H. SIMON, 1965, p.63).

SIMON comments his definition as follows: "In such systems, the **whole** is more than the sum of the **parts**, not in an ultimate, metaphysical sense, but in the important pragmatic sense that, given the properties of the **parts** and the **laws** of their **interactions**, it is not a trivial matter to infer the properties of the **whole**. In the face of **complexity**, an in-principle **reductionist** may be at the same time a pragmatic **holist**" (Ibid).

Thus, the two approaches are by no means exclusive. On the contrary, they should be considered complementary: the first one study the **parts**, **components** of **subsystems**, and the second one investigates the **interactions**.

As shown by SIMON in his "Architecture of **Complexity**" paper, this is by far the tallest order.

Another important point is made by R. ROSEN: "Simple systems do not make **errors**; it is meaningless to regard a system of mechanical particles as behaving erroneously. Therefore there has always been a relation between **complexity** and the capability for **error**" (1991, p.481).

This is consonant with the possibility of alternative **choices** and the need for **decision making**.

J.de ROSNAY describes the complex system in the following way:

- It is composed of a great **variety** of **components** or **elements**, which possess specialized **functions**.
- These **elements** are organized in internal **hierarchical levels**. (For example, in the human body: the **cells**, the **organs**, the systems of **organs**).
- The different **levels** and individual **elements** are connected by a great **variety** of **linkages**. As a result the **density** of the interconnections is very high.
- The **interactions** among the **elements**... are of a peculiar type. They are said to be *non-linear*" (1990, p.96).

This is merely a static **description** of any instant **state** of a complex system. From the **dynamics** viewpoint, as stated by P.M. ALLEN et al: "... complex systems involving **nonlinearities** and **feedback** may possess multiple solutions, and the **bifurcation** of a particular solution is a common **phenomenon**" (1984, p.152). And, at every possible **bifurcation**: "... the system can probe the "validity" of its own **state** of **organization**, and either retain it nevertheless (**stability**), or move away to some other branch of solution, some other **state** of **organization** and perhaps of **complexity**" (Ibid).

According to J.L.LE MOIGNE (1990), a complex system must offer the nine following characteristics: 1) be identifiable; 2) be active; 3) be **regulated**; 4) be informed about its own **behavior**; 5) decide its own **behavior**; 6) be able to memorize; 7) be able to coordinate its **decisions** taken for **action**; 8) be able to imagine and conceive new possible **decisions**; 9) be able to pursue **goals**.

R. ROSEN also offered methodological suggestions about the practical ways to study complex systems:

"a. The only way in which we know how to approach complex systems is to simplify or **abstract** them in some way;

"b. Such simplification amounts to splitting the system into **subsystems**, which are simple enough to be characterized in isolation, and such that our **knowledge** of the isolated **subsystems** can be effectively employed to give us **information** about the original system".

This "splitting", unfortunately, merely reflects DESCARTES old dream, because it eliminates the dynamical **interactions**.

ROSEN himself recognizes this immediately: "In biology, the **abstractions** offered by physical **reductionism** do not in general satisfy proposition b, in that they are not generally compatible with the **dynamics** of the original system" (1972, p.61-2).

For more see: "**Complex system**".

3342

SYSTEM (Composite) ^{1) - 2)}

An almost **homogeneous** system composed of weakly interacting or non-interacting numerous **elements**, similar or pertaining to a reduced number of **classes**.

Such systems should better be named para-systems or quasi-systems, because they lack a number of properties characteristic of more **integrated** systems, as for example:

- they have no definite **function**
- they have no **subsystems**
- they are not **autopoietic**, nor **autonomous**
- they are generally quite **homogeneous**

The **elements** of the composite system are merely in contact, but normally not connected or only weakly connected. Furthermore, its **behavior** is not really integrative and it is not **autonomous** in the **autopoietic** sense, as it is not able to reproduce its **elements**, nor the characteristic **interrelations** among them.

As a result, it must suffer the impacts from its **environment** in a mostly passive way.

However, it may present some characteristic global **states** or **behaviors**, as for example:

- **self organized criticality**
- **spatial self-similarity**
- **percolation processes**
- **runaway processes**.

Examples of composite systems are: heaps of sand, accumulations of snow on mountains, flowing fluids, stock markets, active geological zones, small ecological systems (as, for example, mono- or oligo-cultivation orchards or fields), and possibly star **clusters**.

In some former papers, P. BAK and collaborators used to denominate "dynamic systems", this class of systems which was not very satisfactory, because *all* classes of systems are dynamic.

In the above definition "**homogeneous**" means the opposite of "**heterogeneous**", which is a **state** of highly **complex** and **integrated systems** with many specific and different functional **parts**.

3343

SYSTEM (Conceptual or formal) ^{2) - 3)}

"A system all the **components** of which are concepts" (M. BUNGE, 1993, p.211)

R.L. ACKOFF calls this type of systems "**abstract systems**" (1972, P.84).

According to F. FRISCHKNECHT and J.P.van GIGCH: "Formal systems have three **levels**: vocabulary (terms), **language** (expressions) and system (**production**). Being **isomorphic**, **models** parallel formal systems: **code**, **semantic net** (**data base**), and algebraic **structures**. In the theory of computation, **levels** are called atoms, **frames**, and **states**. Formal systems are closed at both ends, by their primitive terms, and by the **syntax** of their logic" (1989, p.242).

The basic problem with all kinds of formal systems is that they are absolutely limited by the scope of their selected basic concepts. For example, **linear models**, which reflect **linear causal determinism**, are not apt for the interpretation of **nonlinear transformations**.

3344

SYSTEM (Concrete) ^{1) - 2) - 3)}

1a) "An **aggregate** of items that happen to be things (concrete items) and furthermore interrelated in such a way that the **relations** make some difference to the **components**" (M. BUNGE, 1974, p.235).

1b) A set of things, together with the **set** of **connections** among them" (p.229).

2) A system whose "at least two **elements** are **objects**" (R.L. ACKOFF, 1972).

BUNGE equates "concrete" with "material" (1993, p.212). He also writes: "... some of the relations among the **components** of a concrete system are **connections** or links, i.e. every **component** of the system acts on or is acted upon by some other **components** of the same system" (BUNGE, 1974, p.235).

He also states: "On the other hand, a set of **states** of a thing and a collection of **events**, even if ordered, are not concrete systems" (1979, p.7).

And an "... equally pervasive feature of concrete systems is that they react on their **environment**, i.e. that their **output** is never nil (The so-called **machines** without **output**, studied in **automata theory**, are of course fictions)" (1979, p.25).

Correspondingly: "All concrete systems are physical entities, in that they possess **energy** – a measure of changeability... However, some concrete systems are more than just physical entities, in the sense that the **categories** of physics are insufficient to account for them. For example, some are **social systems**" (p.45).

R.L. ACKOFF observes: "In concrete systems establishment of the existence and properties of **elements** and the nature of the relationships between them requires research with an empirical component in it. Such systems, therefore, are the subject of study of the so-called non-formal sciences" (Ibid).

3345

SYSTEM (Connectionist) ²⁾

"A system that contains no explicit **symbols** or **rules**" (J. SUTHERLAND, 1995, p.64).

The commonest kind "are known as **neural nets**" "They consist of **layers** of units, each **layer** connected to the rest at **random**. The first **layer** is triggered by an **input** and the last **layer** represents **output**. The intermediate **layer** or **layers** are called "hidden units". The connections between **layers** are triggered in **parallel**, and their strengths increased or decreased with successive **inputs**" (Ibid).

Two basic characteristics of connectionist systems are that:

- they construct their own **rules** according to successive **responses** to successive **inputs**.
- they are not totally impaired when locally damaged, but only slightly deteriorated.

The **brain** seems to be a connectionist system.

3346

SYSTEM (Conscious) ³⁾

Following A Harry KLOPF, to be conscious, a system must possess two characteristics:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1. It must include a **model** of itself, of its **environment** and of the **relationship** between both
 2. The **information** included in the **model** must be encoded in terms of physical **variables** that are identical with the psychic **variables** we introspectively know (after KLOPF, 1972, p.35).

He adds: "Should the system's **information** be encoded in terms of some other **set** of physical **phenomena**, the system could *behave* as we do but not necessarily *feel* as we do. This is a way of observing that systems may be **isomorphic** with respect to their **behavior** and still differ with respect to their psychic existence" (Ibid, p.37).

One may wonder what precisely the author means by physical **variables** "identical" to psychic **variables** and, even, what is exactly a "psychic **variable**". However his hypothesis about the psychism of eventual non human conscious systems – as for example electronic ones – is arresting.

3347

SYSTEM (Conservative, or Hamiltonian, or non-dissipative) ²⁾

The ideal **model** for a conservative system is the pendulum devoid of friction, which in theory maintains an invariable movement and a constant **energy**.

This type of system may be represented by equations integrable without restrictions and its past and future **behavior** can be completely computed.

The theoretical simplification thus obtained is useful for the prediction of the **behavior** of those **concrete systems** whose **energy** is *nearly* constant and are controlled by only one **dominant variable**, as for example the planets in the solar system.

Perfect conservative systems (which do not exist in the real world), having a constant **energy**, would not be submitted to the **2d. Principle of thermodynamics**, and be perfectly **reversible** and independent from **time** and, thus, have no **attractor**.

"Their **evolution** does not provoke any contraction of the areas in the **phases space**." (P. BERGÉ et al., 1984, p.43).

L. BRILLOUIN did consider this question in depth, starting from POINCARÉ's ideas, in Chapter VI of his book "Vie, Matière et Observation", under the heading: "POINCARÉ: l'Energétique et le déterminisme" (1959, p.195-217). See also his comments on the related LIQUILLE theorem (Ibid, p.181-191).

3348

SYSTEM (Controlled) ¹⁾

According to B. BANATHY, (rigidly) controlled systems offers the following characteristics: "... they are rather *closed* and have only limited and well guarded **interactions** with their **environments**. These types are *restricted*, have

few **components** and operate usually not more than two **levels** of **decision making**. They are *unitary* in **purpose** with clearly defined **goals** and behave *mechanistically*" (1988, p.29).

"... **Operational objectives** and ways and means of **operation** are clearly prescribed; there is little or no room for self-direction at the **operating levels**.

"... Rigid **structure** and well defined **stable relationships** are established among the various system **components**, with little **systems dynamics** and only minor **changes** over **time**...

"Methods that might be appropriate include: **deterministic** methods that rely on quantification and mathematical **representations** and **simulations**, problem focused **operational research** methods, certain **systems engineering** methods, **linear systems analysis**, etc." (Ibid).

BANATHY gives as examples: "**man-machine systems**, assembly line work groups, primitive socio-economic systems" (Ibid). These latter are generally strongly ritualized and thus offer a very restricted **frame** for **activity**.

3349

SYSTEM (Cybernetic) ²⁾

No system can persist if not "cybernetic", i.e. containing **feedbacks**, **regulations** and **controls** (N. WIENER), being endowed with **variety** (W.R. ASHBY), being **autopoietic** (H. MATURANA and F. VARELA), and in **autonomous relations** with its **environment** or **suprasystem** (P. VENDRYES, J.van GIGCH).

R. VALLÉE describes cybernetic systems as follows: "They are **dynamical systems** that possess **input**, **state** and **output**, and consequently an **evolution** equation. Such a system is cybernetic if it is possible to distinguish an **observational** sequence (of the **inputs**), followed by a **decisional** sequence leading to the **effectors organs** (related to **outputs**), being well understood that the **observational** sequence allows the system to observe its **environment** and *itself*. In this way a basic **feedback loop** is instaurated which calls upon various **communication modes** (**transmission** of **perceptions** and **decisions**) which justifies the cybernetic qualification" (1995, p.26).

It ensues from this **description** that cybernetic systems are **co-evolving** with their **environment** (p.89-90).

VALLÉE uses this **understanding** to construct his "**epistemo-praxeology**".

Another interesting description is E. LASZLO's according to whom the general characteristics that cybernetics systems exhibit are:

"1 - **Goal parameters** set in a **control center**

"2 – Sensing **mechanisms** whereby **information** relevant to the system's **goals** is registered in the system.

"3 - **Effector mechanisms** whereby the system acts on its **environment**

"4 - **Transformation rules** or procedures whereby **information** received from the **sensors** is compared with **information** about the **goal-states** and an **error-correcting signal** is produced to modify the **behavior** of the **effectors**".

LASZLO adds: "The **function** of correcting for **deviation** from the **paths** of **goal-attainment** is that of the central **regulator**. It must contain a long term **memory** which stores the system's **norms**, i.e. the **goal-conditions**, which the system pursues by means of its **deviation-reducing behavior**" (1974, p.186).

LASZLO understands that these characteristics are proper to living **organisms** and socio-political systems as well as artificial **control** systems. They are probably inherent to *anything* that could be somehow described as a system: the sun, our planet, an **ecosystem**.

3350

SYSTEM (Decomposable) ²⁾

"A system for which there exists a means of decomposing it into **parts** or **subsystems**" (P.H. ROOSEN – RUNGE, 1966, p.13).

ROOSEN – RUNGE adds: "Only decomposable systems can have a **structure**" (Ibid).

While this is evident, it may to present the concept is ambiguous: A non-decomposable system is no system at all, but only an **element**... if there exists somewhere a non-decomposable **element**! H. SIMON's view of near-decomposability is more precise.

He considers **interactions** between **elements** at different **levels**, which implies that decomposable systems must, in principle, be **hierarchical**. Furthermore, at each **level** he observes the **interactions** between **elements**, that can be strong, moderate or weak (or very active, frequent, or rare). He does this by using **matrixes**.

He also links the evolutive capacity of systems to the frequency of the existence of **stable combinations** between **elements** in defined **neighborhoods**. (This is quite similar to KAUFFMAN's "**frozen cores**"). For him the necessary **time** for a great system to spontaneously **self-organize** from its elementary **components** grows geometrically in relation to the number of the **components**. This is why **evolution** is a **phenomenon** hierarchized in **time**. (see "**Hora and Tempus**" parable).

A curious consequence, also stated by SIMON, is that, if a **hierarchy** of **subsets** exists, in a more or less constant quantity, then the **time** necessary to constitute a system of **n elements** will grow only in relation to **log_n**.

Thus, **hierarchy** provides systems with an evolutive advantage.

SIMON also observes that, when climbing from lower to higher **hierarchic levels**, the **interactions** between **elements** become ever weaker. He gives as an example that, while the **energies** of typical covalent atomic links are in the bracket of 80 to 100 K. calories per mole, the hydrogen energetic links in organic molecules are only about 10 K. calories per mole, and so on. According to SIMON this weaker linking **energies** at higher **hierarchic levels** allows for **transformations** at the higher **level** without **disturbances** at the **level** of the lesser **subsystems**, i.e. guarantees global **stability** (SIMON, 1977 – 1990).

3351

SYSTEM (Description)²⁾

G. KLIR proposes the following conditions as needed for a satisfactory description (in his word "definition") of any system:

"1. It should be based on characteristics traits which we assume to be completely known.

"2. It should be based only on constant traits, since we do not want to consider a **change** of temporary traits as a **change** of the system.

"3. It should be based only on those traits by means of which it is possible to determine all the other (secondary) constant traits; i.e., the definition must neither be overdetermined, nor underdetermined" (1965, p.32).

These conditions are important for KLIR's **re-constructability analysis**.

3352

SYSTEM (Deterministic)²⁾

A system for which "a given **time-invariant** relation among sampling **variables** can be expressed in terms of a **behavior function**" (G. KLIR, 1991, p.58).

In a less abstract and rigorous way, B. BANATHY thus characterizes deterministic systems:

"Systems of this type are more **open** (note: than rigidly **controlled systems**) to their **environment**, but are still closely guarding their **boundaries**. They have more **variables** and the relational arrangement of their **components** is more complex than that of the rigidly controlled type. They still operate in a **mechanistic** mode with clearly defined **purpose** and unity of **goals**

"... **Goals** are clearly set, and **operational objectives** are prescribed. Ways and means of operating are self-selected. This type has some limited self-direction.

"... **Structure** is more complex than that of the rigidly **controlled systems**, and **relationships** among the **components** are also increased. Some minor relational and **structural changes** can be expected to happen through **time**. This type of system is still a **steady-state system**...

"Methods that may be applicable include: **Operations research** and **systems analysis** methods, **living systems process analysis**, **information theory** based on engineering, **negative feedback** based cybernetic methods of systems **control** and **adjustment**, **management by objectives**, etc." (1988, p. 29).

BANATHY gives as examples "traditional bureaucracies, centralized (national) educational systems, small business and industry".

Deterministic systems are ill prepared to cope with turbulent **environments** and are frequently destroyed when confronted to these.

3353

SYSTEM (Dissipative)²⁾

Any system that dissipates **energy**, be it or not able to compensate its losses.

The **structuring** dissipation concept was introduced as early as 1908 by the French physicist H. BÉNARD, but was retrieved from oblivion by I. PRIGOGINE, in relation to his study of **thermodynamics** of systems **far-from-equilibrium**. (starting 1947).

In opposition to **conservative systems**, the dissipative one is dependent on **time** and thus **irreversible** and submitted to an **attractor**, as it dissipates **energy**.

P. BERGE, Y. POMEAU and Ch. VIDAL write: "In some cases... there exists a **function** of the dynamical **variables**, the **Lyapunov function**, which is positive and decreasing in a monotonic way with **time** (*which is a proof of irreversibility*)". However the **Lyapunov function** does not always exist. "A dissipative system may have a **evolution regime** quite more complicated than a simple decrease, when the **dynamics** include at the same time the effects of the **dampening** and a **mechanism** of maintenance of movement which fights this **dampening**" (1984, p.23).

In such cases, the **attractor** may become **fractal**.

3354

SYSTEM (Dynamic)^{1) – 2)}

A system "to which **events** occur, whose **state** changes over **time**" (R.L. ACKOFF, 1972).

ACKOFF also calls it "multi-state".

It is difficult to conceive a system that would not be dynamic. Even very **stable systems**, like fossils, are merely the **present**, and of course not eternal result of a long physico-chemical **transformation**. The expression is thus somewhat tautological!

E. OTT and M. SPANO, who investigate the possibilities of controlling **chaos**, give a more elaborated definition of what they call a dynamical system: "One whose **evolution** is **deterministic** in the sense that its future is determined by its current **state** and past **history**" (1995, p.34).

This definition implicitly contains the possibility of **chaotic behavior**, because of the possible "exponential sensitivity" to **initial conditions**.

3355

SYSTEM (Equifinal)²⁾

"A system that has the property of reaching the same final **state** almost regardless of the **initial state** and **input sequence**" (G. WEINBERG, 1975, p.209).

There is a hidden paradox in this concept. Each system has only one way to go to its final **state**: the experience cannot be repeated. Various systems may of course be compared. But no two systems are identical, so this too is un-conclusive.

The only absolute equifinal property has been deftly described by St. BEER: "Death is equifinal". This reflects basic **thermodynamics**.

3356

SYSTEM (Ergodic)²⁾

A system which will pass through every possible dynamical **state** compatible with its **energy**.

P. COVENEY explains: "...we can use **phases portraits**" to show how an ergodic system behaves. But in this case, we portray the initial **state** of the system as a bundle of points in **phase space**, rather than a single point... In a non-ergodic system, the bundle retains its shape and moves in a periodic fashion over a limited portion of the **space**... In an ergodic system, the bundle maintains its shape but now roves around all parts of the **space**" (1990, p.52).

In a **chaotic system**, "...the bundle, whose volume must remain constant, spreads out into ever finer fibers, like a drop of ink spreading in water; eventually it invades every part of the **space**. This is a consequence of what is called LIOUVILLE's theorem... The total probability must be conserved (and add up to 1): the bundle behaves like an incompressible fluid drop. This is an example of a "mixing ergodic flow" and manifests an approach to **thermodynamic equilibrium** when the **time evolution** ceases" (Ibid.).

An ergodic system is thus the one for which the global **set** of **trajectories** if well defined, while individual ones remain probabilistic.

About **ergodicity** of **Markovian systems**, G. PASK writes: "... the **state** (Note: i.e. the **global state**) of the **Markovian system** is invariant and it can be shown that the values in the **distribution p^*** are independent of the initial **state i** . But any **representative system** can move away from any **state** to any other **state**. In the **phase space** the **state** points of the ensemble are in continual motion, because a **representative system** can always reach any of the **states** (none of the **transitions** are impossible), the

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

average **population**, at any instant, being determined by p^* . The **equilibrium** is called ergodic and the set of **states** which can be visited (in this case all the **states**) is called an **ergodic set**" (PASK, 1961a p.122-3).

PASK shows furthermore that a system can be at the same time ergodic and **cyclic**.

As proved by KOLMOGOROV, a basically non-ergodic system may however contain ergodic bundles or regions (S. DINER, 1992, p.355).

3357

SYSTEM (Exosomatic) ⁴⁾

The global **human system** which is based on, but enfolds, the genetic and the cultural system.

S. GOONATILAKE, who introduces this concept, understands that the accelerating **growth** of global **information** systems is leading to a kind of meta-control over the biological and social **strata** of **human systems**, through integrating **flow lines** of **information**, which enhance cohesiveness by **symbols** transmission (1991, p.83-85).

3358

SYSTEM (Far-from-equilibrium) ²⁾

A system far-from-equilibrium undergoes wide **fluctuations** and may come very close to a **threshold of instability**. A still wider **fluctuation** may cause it to cross such a **threshold**, which becomes a **bifurcation** point where the system may jump to another **steady state**. In **chaotic systems**, such **bifurcations** may become quite frequent, creating a multiplicity of possible **fractal stability basins**. Sometimes, beyond such a crisis point a higher organized **state** may emerge, associated with a higher **level** of **entropy** production (I. PRIGOGINE).

3359

SYSTEM (Formal) ²⁾

"A collection of abstract **symbols**, together with a **set** of **rules** for assembling the **symbols** into strings" (J. CASTI, 1994, p.121).

CASTI adds to this definition: "Such a system has four **components**:

"**Alphabet**: This is simply the **set** of abstract **symbols** themselves. These may be as primitive as the **symbols** + and -. But they could also be much more concrete, such as the characters of the latin **alphabet**, along with the **symbols** for punctuation, logical **combination** and the like

"**Grammar**: The grammatical **rules** of the system specify the valid ways in which we can combine the **symbols** of the **alphabet** to form finite strings (words), as well as how such strings may be combined into large statements. Statements of this type are termed *well-formed*.

"**Axioms**: A set of well-formed statements that are taken as given strings of the system are called axioms... Thus, an axiom is a string of **symbols** that we accept as a valid statement *without its having to be proved* (italics ours).

"**Rules of inference**: These are the procedures by which we combine and change axioms and other well-formed statements into new well-formed strings" (1994, p.121).

CASTI adds an important caveat: "... it is evident that in a very definite sense the theorems of a formal system are already present in the axioms and **rules of inference**. All a proof sequence does it to make explicit that which is already implicit" (p.123).

Thus formal systems are *closed* and, for this reason, submitted to the limits of **GÖDEL's incompleteness theorem**.

3360

SYSTEM (Generative) ²⁾

Any systemic **model** sufficiently general to be used to represent the **set** of possible **transformations** for a **category** of systems.

G. KLIR states: "Since the overall relations among basic **variables** and those derived from them by various **translation rules** (e.g. **lagged variables**) can be utilized for describing a **process** by which **states** of the basic **variables** are generated within the delimited **support set**, systems on this **level** are called generative systems".

KLIR gives as examples: "Finite-state **machines** (deterministic or probabilistic), **Markov chains**, and differential equations with constant coefficients", and adds: "Each of them characterizes a relation among the **variables** involved, which does not change with the relevant **support set** (**time** or **space set**). This relation makes it possible to generate specific **data sets**, one for each initial or **boundary condition** and for a given **support set**" (1991, p.53).

3361

SYSTEM (Goal directed) ^{1) - 3)}

Any well integrated system may be considered as a goal-directed, i.e., tending or trying to reach some precise and (more or less) permanent goal.

However, this concept is a difficult one.

A **composite system**, endowed with a very low degree of **integration**, tends to go back to its characteristic **critical states**. However this has obviously no volitive undertones: it is just what a loose, but not totally unrelated variable mass of **elements** *does*, due to mere physical **random interactions**. This could be qualified either as **dynamical stability** or instability!

A more integrated system acquires **organizational closure** and **autopoiesis** (i.e. **self-reproduction** capacity) and its global goal is thus inscribed into its internal logic, i.e. to maintain itself in existence.

By stages, from simple **living systems** to the highest and most complex and integrated ones, a growing measure of **self-regulating** capacity leads to the voluntary manipulation of inside and outside **regulations**, which become "**control for**", through manipulation of the **environment** and **anticipatory adaptation** through **feedforward**. Thus, "goal directed" evolves into "goal seeking" in a conscious sense.

Besides, in **complex systems**, the global **survival goal** may become subdivided into a great number of auxiliary **goals**, sometimes **hierarchized**, and whose harmonization may become a very difficult problem.

G. KLIR discussed "goal-oriented systems" and multigoal-oriented systems" in a very close **meaning** and proposed interesting ways to modelize them (1991, p.143-161).

It is also somewhat difficult to draw a precise separation line between "goal-oriented" and "**goal-seeking**" systems (see hereafter).

3362

SYSTEM (Goal-seeking) ^{1) - 3)}

"(A system) that can respond differently to one or more different external or internal **events** in one or more different external or internal **states** and that can respond differently to a particular **event** in an unchanging **environment** until it produces a particular **state** (outcome)" (R.L. ACKOFF, 1972).

R.L. ACKOFF explains: "Production of this **state** is its **goal**. Thus such a system has a *choice of behavior*. A goal-seeking system is **responsive**, but not **reactive**. A **state** which is sufficient and thus deterministically causes a **reaction** cannot cause different **reactions** in the same **environment**" (Ibid).

Thus, a goal-seeking system is endowed with some measure of **autonomy**.

→ "**Goal-seeking system**".

3363

SYSTEM (Heterogeneous) ^{1) - 2)}

A system made of different classes of complementary **components** and **subsystems**.

Any system is heterogeneous, but it is a matter of degree. Heterogeneity is a necessity, in accordance to the **law of requisite variety**, for good **adaptiveness**. Heterogeneity does not however precludes **organization**, which is needed for **coherence**.

The most **complex systems** are also the most heterogeneous ones.

3364

SYSTEM (Heuristic) ^{1) - 2) - 4)}

A system that can formulate its own **goals** and **objectives** (Adapted from B. BANATHY, 1988, p.29).

Only human systems are heuristic.

BANATHY describes them as "... *complex* and *systemic* in their **functional** and **structural** arrangements and... *open* to, and *coevolving* with their **environments**.

"Overall **policy** is set for heuristic systems; and within their **policy framework goals, objectives**, ways and **means**, and **methods of operation** are self-selected.

"Significant relational **changes** and some **structural changes** may occur through **time**. **State changes** are evolutionary and are directed by **design**. **Emergence**, **ambiguity** and **uncertainty** surround **state changes**.

"**Methods** in general are built upon **cybernetics** and **general systems theory**, and systems based organizational theories. Applicable **methods** include **living systems process analysis**, **systems design**, **soft-systems methods of analysis and management**, **double-loop organizational learning** and **consensus building**" (Ibid).

Furthermore, heuristic systems "... have to learn to cope with the explosive increase of relevant **knowledge**, **environmental complexity** and **turbulence**. Furthermore, the **changes** faced... increase as to their intensity, **variety** and dimensionality" (Ibid, p.31).

3365

SYSTEM (Hierarchic) ^{1) - 2)}

"A system that is composed of **interrelated subsystems**, each of the latter being, in turn, hierarchic in **structure** until we reach some lowest **level of elementary subsystem**" (H. SIMON, 1965, p.64).

The **concept** has been put to good use by SIMON in his parable about the two rival watchmakers "**Hora and Tempus**", which shows how to use the **recursive** character of hierarchy for the practical study (and guidance!) of hierarchic systems.

The definition of the "lowest elementary **subsystem**" (or **module**) is however a **modeling decision** to be taken.

Altogether, not all systems are hierarchic, at least in their formation **period**. **Networks** seem to be self-constructing their **organization**, which does not seem to be necessarily hierarchic.

In any case, SIMON's concept and **model** are very useful to clear the hierarchy concept of its authoritarian overtones, giving it a purely **organizational meaning**.

Transversal and bi- or multi-lateral **interrelations** among and between **subsystems** are not, and should not be, excluded under the hierarchical **order** concept. (see "**Heterarchy**")

→ "**System (nearly decomposable)**"

3366

SYSTEM (Homeostatic) ^{1) - 2)}

A system that remains static while its **elements** and **environment** are dynamic.

This definition is adapted from R.L. ACKOFF, who explains: "Thus a homeostatic system is one that retains its **state** in a changing **environment** by internal **adjustments**. A house that maintains a constant temperature during changing external temperatures is homeostatic. The **behavior** of its heating **subsystem** makes this possible" (1972, p.85).

Comparing this concept with W. CANNON's one, it would seem somewhat too narrow.

It could be argued that the homeostatic system is static only "by and large", and this, furthermore in two different senses. First, such a system really oscillates within a more or less narrow band of possible **states** determined by the unavoidable **feedback delays** of its **controls**.

Secondly, **concrete systems** incur in an **ageing process** which slowly modifies their general **state** in an **irreversible** way.

3367

SYSTEM (How to define the meaning of a) ^{1) - 4)}

C. WEST CHURCHMAN writes (1991, p 29-30): "... we can outline five basic considerations that the scientist believes must be kept in mind when thinking about the meaning of a system:

1. The total system **objectives** and, more specifically, the performance measures of the whole system.
2. The system's **environment** (the fixed **constraints**).
3. The **resources** of the system.
4. The **components** of the system, their **activities**, **goals**, and measures of performance.
5. The **management** of the system."

Obviously, this listing refers to human organizational systems and should be adapted for different classes of systems like physical, biological, mechanical ones, for example.

3368

SYSTEM (Hypothesis of the lone) ³⁾

R. VALLÉE proposes the hypothesis of the "lone system", being an observing system unique in a given **environment** and emphasizes the difference in its quality of **knowledge** "as compared with the case of a collectivity of such systems" (1991a, p.143).

A lone system exists within a **universe** that it is able to know only within the limitations of its own perceptive and interpretative capacity. It can be said that it remains secluded within its own epistemological ability (VALLÉE's "**epistemological subjectivity**").

Its relation with its **universe** depends on its own characteristics as an **observation operator** and on its aptness as a **decision operator**. VALLÉE makes clear that "We suppose furthermore that the system is what we call a *cybernetic system*, i.e. a system able to observe its **environment** and itself" (Ibid).

On such a base the system can observe, decide and act, modifying its **environment** and itself, but strictly within the limits of its so-called **epistemological subjectivity**. This situation is unavoidable and could be improved only to a point by **conversation** and **consensus** among various systems within a common **environment**.

3369

SYSTEM (Ideal-seeking) ⁴⁾

"... a **purposeful system** which, on attainment of any of its **goals** or **objectives**, then seeks another **goal** and **objective**, which more closely approximates its ideal" (R.L. ACKOFF, 1972).

According to ACKOFF: "An ideal-seeking system is thus one which has a concept of 'perfection' or the 'ultimate desirable' and pursues it systematically; that is in interrelated steps" (Ibid).

Some question marks remain:

1. what is "perfection" or the "ultimate desirable"?
2. and, if it can be defined, in which way can the system construct it?

3370

SYSTEM (Input-output)

→ **Input-output matrixes**

3371

SYSTEM (Integrated) ^{2) - 4)}

A system whose **components**, **parts** or **subsystems** are strongly interconnected and interacting.

Strictly speaking, a system that would not be at least minimally integrated would not be a system at all. However, a vegetal, animal or human **colonial system**, for instance, is looser than a biological one.

In an integrated system, **processes** and **functions** are permanently and closely interdependent. Their **relations** are **regulated** by a **hierarchy of controls**. The system cannot survive the complete destruction or impairment of any of its **critical subsystems**, nor the severance of their **interactions**. None of the **subsystems** can normally survive outside of the system.

Integrated systems are also characterized by the existence of an internal **environment (in-vi-ron-ment)**, of which the **subsystems** depend for their **survival** and which they collectively maintain. The most integrated the system, the lesser the number of its **elements** that interact directly with the **environment**.

Biological systems are more integrated than **ecosystems** and these, in turn, more so than **composite systems**. Man seems to be the most complex integrated **living system**, due mainly to the capacity to pick up and **process information**.

Systems that become too strongly integrated run the risk to become rigid and blocked, thus loosing **adaptive** capacity, and risking destruction. The demise of U.R.S.S. was a good example.

3372

SYSTEM (Irreversible)¹⁾

Any **concrete system**, as a necessary user of **energy**, is unavoidably **irreversible**, as a consequence of the **2nd law of thermodynamics**. It may however be **dynamically stable** (PRIGOGINE's Principle of **minimum entropy production**) or be **far-from-equilibrium** and **dissipative**.

Only **models of hamiltonian** systems are in principle reversible. But this is possible only in theory or at most for the **modelization** of relatively simple and strictly **deterministic relations**.

3373

SYSTEM (Isolated)²⁾

A system that makes no exchange of any kind with any **environment**.

As stated by I. PRIGOGINE and P.M. ALLEN such a system: "... whatever its nature, will approach **thermodynamic equilibrium**, a **state** characterized by the maximum value of **entropy**, that is of "**disorder**" (1982, p.5).

This is a largely abstract concept. Indeed it is the **model** of a system rigorously submitted to the **2d law of thermodynamics**.

By definition the isolated system does not absorb nor emit any **energy, matter** or **information** and could thus not even be observed. While useful in classical physics and chemistry, it can not be used in biology nor social sciences (nor even, in some cases in physical sciences). This explains why classical **thermodynamics** had to be extended during this century to **open and irreversible systems**.

According to G. SOMMERHOFF: "An isolated physical system in the classical sense is determined by the **initial state**". This means "that the current **state** of the system can be expressed in terms of single-valued **functions** of the **initial state** and the **time**". SOMMERHOFF gives the example of the pendulum, for which

the isolated system **model** does not take in account any friction or **disturbance**, which, of course, are always acting on **concrete systems**.

The isolated system, furthermore is practically always **linear** and generally **deterministic**. G. SOMMERHOFF writes about this point: "In a **state-determined system** every possible initial **state** determines a single line of **behavior** only. And although different lines of **behavior** may at one point or another fuse, *they can never bifurcate*" (1969, p.158).

The concept of isolated system is particularly confusing in the case of **living and social systems**. As stated by A. RAPOPORT: "an isolated system cannot be a **living system** (at least not for long)" (1966, p.6).

The misunderstanding of this aspect, very common since DRIESCH vitalism until the 1930es, blocked partly the development of biology during half a century, with among exceptions, WOODGER and von BERTALANFFY's work.

3374

SYSTEM (Isomorphic)

A system whose all characteristics would be in a one-to-one correspondance with all those of another system.

This is clearly another semantic inconvenience: No two systems are ever identical.

It would merely be conceivable that the *models* with selected characteristics taken out of two *similar* systems, could be isomorphic.

But we may be satisfied with partial isomorphies, that can be very useful to create generalizing **models**.

→ **SYSTEMS (Isomorphic)**

3375

SYSTEM (Life cycle of a)¹⁾

All systems – except possibly the most elemental particles described or postulated by micro-physics – go through a **life cycle**, that can be described chronologically as follows:

- **autogenesis**: shaping of the entity (**entitation**) by **association** of formerly independent **elements** (V. CSANYI);
- **morphogenesis**: structural and functional **development** of the system by internal **differentiation** or/and absorption and **assimilation** of external **elements**;
- **homeostasis**: structural and functional **stabilization** of the system, with **fluctuations** within **limits**;
- **sclerosis**: by progressive reduction of the **fluctuation** and **regulation** capacity;
- **dissolution**: terminal loss of **coherence, heterogeneity** and **identity** and dispersal of the constitutive **elements**.

This is even true for very stable atoms caught in some cosmic cataclysm.

However, in some cases, a system may leave some trace (as for example petrified "wood", which is in fact stone).

H. PRAT called these traces "**aura**".

3376

SYSTEM (Linear)²⁾

A system which responds to an increase or decrease of some **input** by a **change** of the same amount in its corresponding **variable**.

Only very simple systems, in fact simple **functions**, if they may be called systems, can be linear. The real condition of **linearity** is that the system be very poorly **joined** in ASHBY's sense, i.e. devoid of significant internal **interactions, constraints** and **feedbacks**. No **complex system** can be linear more than in a very limited, local and provisional sense.

R. VALLÉE provides a good global overview of dynamic linear systems of differential nature (**continuous**) or recurrent (**discrete time**) (1992, p.114-26).

3377

SYSTEM (Man-machine)^{1) - 2)}

A system composed of a **subsystem** of inter-connected functional **artefacts** (the "machine") and a human individual or groupal **subsystem** which steers or **control** it.

In our technological civilization, there are countless man-machine systems, which are evolving toward an ever-increasing **complexity**, generally characterized by a growing **automation**, and **autonomy**, of the machine **subsystem**.

Man-machine systems are the specific field of study of **systems engineering**.

3378

SYSTEM (META-) TRANSITION²⁾

Transition toward a higher **level of control** in a system.

Such a **process** may take place when the existing cognitive **subsystem** is no longer able to cope with a growing **complexity**, which happens "...if the **variety** of possible actions is larger than (its) capacity for **control**." (F. HEYLIGHEN, 1991).

Through this kind of **complexity emergence** "... a number of **control** systems are integrated into a single **whole** with the formation of a global **control system**" (Ibid).

HEYLIGHEN adds: "...the **emergence of control** leads to an increase of **variety**, whereas the increase of **variety**, if it is large enough, stimulates the **emergence** of a new **control** in a **positive feedback cycle**" (Ibid).

In this way a **hierarchy of controls** builds progressively up. Furthermore: "... once the **control** at the higher or meta-level has emerged, the number of **subsystems** it controls will in general increase. V. TURCHIN calls this **phenomenon the branching growth of the penultimate level**" (Ibid).

→ **Meta System Transition**

3379

SYSTEM (Multi-Agent)

→ **Multi-Agent System**

3380

SYSTEM (Multi-level)²⁾

A multi-level system is not necessarily rigidly **hierarchical** in a unique vertical line of command.

There may exist **communication** lines within the same level between different **subsystems**, and possibly some local **hierarchies** at intermediate levels. Various partial or local **hierarchies** may become unified only at the uppermost level.

Abilities and **regulations** may even be more or less diffuse under the form of local but interconnected **networks**, allowing for a **heterarchical** and **holographic organization**.

3381

SYSTEM (Multistable)²⁾

A system "which consists of many **ultrastable systems**, joined main **variable** to main **variable**, all the main **variables** being part **functions**" (W.R. ASHBY, 1960, p.171).

3382

SYSTEM (Near Equilibrium)²⁾

"Any system characterized by an irreversible **evolution** towards a fixed stationary **state**, called **attractor**" (S.H. STROGATZ & I. STEWART, 1990, p.100-1).

"This type of systems may be described by a quite precise equation, which permits to compute the **stationary state** towards which they tend. Examples of open **dissipative systems near equilibrium** (i.e., which have a **linear** movement equation) are numerous: slow flowing rivers, heat **flow** through a partition, common chemical reactions, motors, etc..." (Ibid).

They are characterized by an "**evolution of entropic type**" "**attracted**" by the most probable **state**, the one of maximum **disorder** (or the one of **stationary state** of the same type...)" (Ibid).

This type of system can however maintain itself in a regime of **dynamic stability** during a more or less protracted **period**, while stabilizing its **entropy** production to the lowest **level** compatible with its characteristics.

When the system finally reaches its **attractor**, it destroys itself as a system and its **elements** recover their **independence**.

3383

SYSTEM (Nearly decomposable)^{1) - 2)}

A system "in which the **interactions** among the **subsystems** are weak, but not negligible" (H. SIMON, 1965, p.69).

The subsystems and their **interactions** can generally be represented in a **matrix** divided into submatrixes, wherein most intersections between columns and lines are void.

SIMON enounces the following propositions relative to these systems:

"a) ... the short run **behavior** of each of the **component subsystems** is approximately **independent** of the short-run **behavior** of the other **components**;

"b) in the long run, the **behavior** of any one of the **components** depends in only an aggregate way on the **behavior** of the other **components**" (Ibid).

SIMON adds: "intra-component **linkages** are generally stronger than intercomponent **linkages**. This fact has the effect of separating the high-frequency **dynamics** of a **hierarchy** - involving the internal **structure** of the **components** - from the low-frequency **dynamics** - involving **interaction** among **components**" (p.72).

According to SIMON, the nearly decomposable system **model** can be widely used, for **social** and **economic systems**, as well as for many physico-chemical systems, whose **parts** are very imperfectly connected.

3384

SYSTEM (Nondeterministic)²⁾

A system in which "the **states** of the generated **variables**... are not determined uniquely by the **states** of the generating **variables**" (G. KLIR, 1991, p.56).

KLIR adds: "Instead, they are generated with some uncertainty, which may, for example, be expressed in terms of conditional **probabilities**... called **behavioral probabilities**" (Ibid).

This is the case for **ergodic systems** and, possibly for **chaotic** ones.

3385

SYSTEM (Nonequilibrium)²⁾

Any system that "... through internal **amplification** or **fluctuations**, may cross **instability thresholds** and form... **dissipative structures**" (E. JANTSCH & C. WADDINGTON, 1976, p.71).

The theory of nonequilibrium systems has been firmly established by I. PRIGOGINE.

The appearance of **dissipative structures** corresponds to the **emergence** of "... new **dynamic regimes** which represent a new ordering principle beyond the thermodynamic branch

(which describes **order** near **equilibrium**). Such **dissipative structures** can be maintained only through **energy** exchange with the **environment**" (Ibid., p.72).

When the new **dissipative structures** become stabilized, the emerged system may settle down at a higher **level** of **entropy** production and thus reach a new **equilibrium** at this corresponding higher **level** of **complexity**.

3386

SYSTEM (Nonlinear)²⁾

Any system with various simultaneously **interacting** causal lines that impede rigorous globally **deterministic behavior**.

L. DOUGLAS KIEL writes: "Linear systems respond to minimal **changes** in their **parameters**, or to external shocks, in a smooth and proportionate manner" (1992, p.30).

It is really very difficult to conceive a system which would be truly **linear**. **Models** of systems are frequently **linear**, indeed. But their **reliability** is generally limited to a small and **short term range** of the system's **behavior**.

DOUGLAS KIEL writes: "A small **change** in a nonlinear system can, however, produce an enormous difference in the **structure** and **behavior** of the system" (Ibid).

However, many small **changes** have no such effects, with the result that we may well believe in a non-existent **long term dynamic** (or even static !) **stability**.

"... external **disturbances** may amplify nonlinear **interactions**, generating **instabilities**, that may initiate a break with the pre-existing **behavioral** and **structural regimes**" (Ibid).

"Nonlinear systems may also reveal a "sensitive dependence on **initial conditions**" (J. GLEICK, 1987).

"A small difference in the **initial conditions** of seemingly similar nonlinear systems can lead to dramatically different evolutionary **paths** and outcomes. ...Any effort at **forecasting** the **behavior** of a nonlinear system is, thus a highly suspect activity" (Ibid).

This is possibly somewhat over-pessimistic: With good **monitoring**, a sufficient grasp of **chaos theory**, and as much as possible consolidated **knowledge** of the various **levels** of **cyclical activity** of the system, some **forecasting** is feasible... but the results should always be taken with caution.

According to DOUGLAS KIEL: "Nonlinear systems exhibit four distinct types of temporal **behavior**...

1) **convergence** to a **stability** or **equilibrium**

2) stable **oscillation**

3) unstable and explosive

4) **chaotic**.

Each regime can appear within the **long term behavior** of a nonlinear system" (Ibid).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Another important aspect is, in P.M. ALLEN et al. words: "... nonlinear systems, operating far from thermodynamic equilibrium, can undergo successive structural instabilities leading to a progressive complexification of their organization and functioning. Such phenomena involve a dialogue between stochastic and deterministic aspects of the system, as the interaction tend to a "self-organization" process of successive periods of stability and instability, where new qualities, traits and characteristic emerge over time" (1984, p.150).

Evolution seems thus to offer a "punctuated" character, as claimed in living systems by GOULD and ELDREDGE.

3387

SYSTEM (Open) ²⁾

A system able to selectively exchange matter, energy and/or information with its environment.

The selectivity is the key aspect, in space as well as in time. The system can be alternatively open or closed to some inputs or outputs. This means that the system has a more or less extensive capability to control its inputs and outputs in relation to its needs. This secures the individuality of the system and connects the open system concept with the autopoiesis and organizational closure ones.

R. ROSEN expresses the consequences as follows: "von BERTALANFFY explicitly showed that a basic characteristic of biological systems could be approached entirely through a functional or relational criterion (i.e. that the system be open) rather than through reductionist analysis of the specific particles of which any particular system happens to be composed".

"(He also stressed) the relation between regulatory phenomena in biology, particularly those which appear to involve purposiveness, and the formal concept of stability" (1973, p.176).

Furthermore, ROSEN adds that von BERTALANFFY had an implicit intuition that the classical thermodynamics was at a loss to explain living systems, a fact that was later explained by I. PRIGOGINE, who introduced the needed amendments. And finally, von BERTALANFFY recognized that an open system could reach the same final state, using different lines of behavior (equifinality).

D. KATZ and R.L. KAHN describe as follows the main characteristics of open systems:

"- They undergo "repeated cycles of input, transformation, output, and renewed input
"- The law of negative entropy (?) states that systems survive and maintain their characteristic internal order only so long as they import from the environment more energy than they expend in the process of transformation and exportation" (1969,p.103). (The excess is used to maintain internal order ... through the pro-

duction of new elements characteristic of the system and used to replace elements of the same type).

"- They possess feedback devices that KATZ and KAHN interpret as follows: "The feedback principle has to do with information output, which is a special kind of energetic importation, a kind of signal to the system about environmental conditions and about the functioning of the system in relation to its environment... The system thus maintains a steady state or homeostasis. This is a dynamic rather than a static balance, however" (Ibid).

"- They tend to differentiation and elaboration, both because of subsystem dynamics and because of the relationship between growth and survival" (Ibid).

"- They are equifinal which means "... that systems can reach the same final state from different initial conditions and by different paths of development" (Ibid).

3388

SYSTEM (Organismic) ^{2) - 5)}

"An open system which either is an organism or can be treated as an organism, where the chief characteristics of an organism are relatively fixed ordering of components, reproduction of the same type or species, and the existence of a life cycle" (O.R. YOUNG, 1964, p.70).

According to YOUNG, the concept, basic in von BERTALANFFY's work, is usable in biology, economics, sociology and political sciences.

Organismic systems are necessarily autopoietic, i.e. endowed with organizational closure.

3389

SYSTEM (Oscillating) ²⁾

A system that fluctuates more or less periodically between defined stability limits.

There is a great variety of oscillations modes, from the perfectly regular to the most complex, and even more or less random as in ergodic systems.

Probably all dynamically stable systems can be considered as oscillators, submitted, in HAKEN's terms, to an order parameter.

However, a system submitted to growing oscillations may run out of control, enter in a far-from-equilibrium situation, reach a bifurcation point and start to produce new dissipative structures. When (and if) it reaches a new minimum entropy producing equilibrium it turns to a new oscillating mode.

→ Oscillators

3390

SYSTEM (Polystable) ^{1) - 2) - 4)}

"Any system whose parts have many equilibria and that has been formed by taking parts at random and joined at random" (W.R. ASHBY 1960, p.173).

What ASHBY has in mind are systems whose parts are "... assured to be state-determined, and thus to have (in themselves) no randomness at all" (Ibid).

Some examples are von FOERSTER's small magnets in his famous "order from noise" experiment, or better still, neurons - natural or artificial.

What ASHBY wants to study is the way such elements, when joined, start to organize themselves spontaneously.

He sums up the result of such a process in the following way: "The polystable system, if composed of parts whose states of equilibrium are distributed independently of the states of their inputs, goes to a final equilibrium in a way that depends much on the amount of functional connection" (p.178).

He adds: "When the connection is rich, the line of behavior tends to be complex and, if n is large, exceedingly long; so the whole tends to take an exceedingly long time to come to equilibrium" (Ibid). As possible examples (admittedly hypothetical) we may consider any complex society, like neurons in the brain or people with diversified roles in a numerous human organization.

ASHBY completes his comment saying: "When the connection is poor (either by few primary joins or by many constancies in the parts), the line of behavior tends to be short, so that the whole arrives at a state of equilibrium soon" (Ibid).

ASHBY's own quite simple homeostat is a good example.

3391

SYSTEM (Primitive)

→ System (Source)

3392

SYSTEM (Probabilistic) ²⁾

A system made from more or less unreliable components.

J.von NEUMANN demonstrated the possibility to construct a globally reliable system from components whose behavior is probabilistic (1956, p.43-98).

This is the case for networks with very numerous components and links among them, probably because a global order appears spontaneously and supersedes local disturbances.

ASHBY's homeostat, as the behavior of its elements becomes ordered as a Markovian process (1958, p.232-4) is also a probabilistic system.

3393

SYSTEM (Purpose seeking) ^{1) - 4)}

B. BANATHY describe this type of systems "... as complex, ideal-seeking systems guided by **images** of the future that they shape themselves". Of course, ideal-seeking systems should not be confused with ideologically constructed ones (but may be sometimes in serious danger to be).

BANATHY states: "They are both *open* and *adaptive* to the **environment** and are shapers of the **environment**. They are *pluralist* and thus able to seek and explore new purposes. They are *systemic* in their arrangements and **behavior**. They exhibit such qualities as **emergence**, self-transcendence, and a tendency for **cooperation** and even **integration** with other systems and reorganization at a higher **level of complexity**" (1988, p.30).

As to their degree of self-direction: "**Policies** are formulated based on **images** of the future that people in the system shape collectively. There is constant search for new purposes; new **niches** in the **environment** that the system can carve out, shape, or incorporate".

As to their **structure/relational state**: "Significant structural **changes** may occur through **time**. **State changes** may be independent of prior **states**. Discontinuity and reorganization at higher **levels of complexity** are expected to happen, directed by purposeful **design**. **Ambiguity** and **uncertainty** are used creatively" (ibid).

Some of the examples given by BANATHY are: "... seeking and designing new institutional roles for the private and public sector; seeking society renewal through the **design** of integrative **community** systems, the **design** of alternative educational systems,... peace development and alternative security systems" (ibid).

This type of systems closely corresponds to JANTSCH's "**purposeful systems**" (1975).

3394

SYSTEM (Purposeful) ^{1) - 4)}

"(A system) which can produce the same outcome in different ways in the same - internal or external - **state** and can produce different outcomes in the same and different **states**" (R.L. ACKOFF, 1972).

Such systems may be **equifinal**.

R.L. ACKOFF explains: "Thus a purposeful system is one which can change its **goals** under constant conditions; it selects ends as well as means and thus displays *will*. Human beings are the most familiar examples of such systems".

He adds: "A system which can choose between different outcomes can place different **values** on different outcomes" (1972, p.87).

This leads ACKOFF to the **concept** of **ideal-seeking system**.

Pursuing this line of thought, W. ULRICH advocates for a "purposeful systems **paradigm**". This idea is synthesized by R.L. FLOOD and M.C. JACKSON: "... in a purposeful system, the ability to determine the purpose must be spread throughout the system; the system should produce **knowledge** relevant to purposes and encourage debate about purposes; and all plans or proposals for **design** should be critically assessed in terms of their normative **content**. **Critical systems heuristics** is about the **design** and assessment of purposeful systems" (1991, p.203).

This trend is now visible in S. BEER's **Viable System Model**; in J. WARFIELD's **Generic Design**; in the FUSCHL type **Conversations**; in J.A. JOHANNESSEN's **Holographic model**; in I.I. MITROFF and H.A. LINSTONE's **Unbounded System Thinking** and in R.L. FLOOD and M.C. JACKSON's **Total Systems Intervention**.

3395

SYSTEM (Purposive) ²⁾

"A **multi-goal-seeking system** the different **goals** of which have a common property" (R.L. ACKOFF, 1972).

ACKOFF explains: "Production of that common property is the system's purpose. These types of system can pursue different **goals** but they do not select the **goal** to be pursued. The **goal** is determined by the initiating **event**. But such a system does choose the means by which to pursue its **goals**" (ibid).

A computer with a **variety of programs** is thus a purposive system (to be distinguished from a **purposeful system** - see above).

B. BANATHY gives the following characteristics of this type of systems:

"Degree of self-direction. Purposes are set for the system, **strategic goals** are prescribed, however operational **objectives**, **methods** and means of **operation** are self-selected.

"(As to the) **structure/relational state**: **State changes** are gradual, influenced primarily by **environmental changes** that indicate the need for **adaptation**. **Structural change** happen slowly over **time** and are coupled with **changes** in systemic **relationships**. Increasing **complexity** in this system type indicates **multi-level hierarchy** and **embeddedness**. Purposive systems may embed **deterministic** and rigidly **controlled** systems.

"**Methods** that are relevant for this type may include those based on cybernetic theory, **systems analysis**, **systems engineering** and **systems design**. **Living systems theory** has special relevance for purposive systems in view of the significance of **information** and **matter** and **energy** processing in these systems. Having freedom for selecting **objectives**, **consensus building methods** also come to play in purposive systems" (1988, p.29).

An interesting comparison can be made with **heuristic systems**.

3396

SYSTEM (Quasi-Periodic) ²⁾

A system submitted to a merely general, but imprecise **determinism** in **time**.

Quasi-periodic systems successive **states**, or **trajectories** are submitted to a **toric attractor**. The **trajectory** does practically never come back exactly to the same point. It remains however within globally stable **limits**.

→ **Quasi-periodic**

3397

SYSTEM (Relevant)

A **human activity system** whose modeling is considered necessary by a manager or an **observer**" (Adapted from R. RODRIGUEZ ULLOA, 1994)

The crux of the issue is in the word "relevant" !

From one side, there may be different views about what are the relevant characteristics of the system. Managers for ex., in many cases consider relevant only those features that are determinant from an economic viewpoint. A union leader or a sociologist may have a different interest.

As to the modelizer, relevance is frequently a matter of selecting **variables** that have a real influence on the system's **behavior** (and at which **time horizon**). His views are not necessarily shared with the "owner(s)" of the problem and it may be difficult to convince them. They may even not be shared among modelizer's themselves!

3398

SYSTEM (Richly or poorly joined) ²⁾

W.R. ASHBY states that a system may have more or less strong or weak internal interactions among its **parts** or **subsystems** (1960, chap.11).

A totally joined system would become at the same time clogged and blocked; if any **element** can communicate freely with any other *at any time* and in any way, no **order** can be defined. Curiously, the result is the same as in a collection of disordered **elements** (the case of the totally entropized **isolated system** - a semantic contradiction, since such a system does not possess anymore any feature).

Thus, a system can be functionally defined only if it is *limitedly* intra-connected, i.e. if its **variety** is limited by **constraints**, i.e., if some **interrelations** are not permitted.

Furthermore there seems to exist an optimum such as the system reaches at one moment the best adapted **level of internal connection** in relation to its functionality, while at the same time, maintaining the best possible **adaptativeness**. Such an optimum must however necessarily be transitional.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

One could also speak of strongly or weakly intraconnected system to make more understandable the somewhat at times esoteric language of ASHBY.

3399

SYSTEM (Second Order)²⁾

"A chain of two storing units (Integrators) with a loopback" (H. ODUM, 1971, p.99).

This is a **systems engineering** concept. It is thus called "... because the differential equation for the whole system has a second derivative. Such systems may oscillate regularly, and when the **input** is variable, undesirably wide **fluctuations** may result. The **oscillator** may get into **phase** with the external **variation** of **input** and go into **resonance** with **variations** and **flows** that are larger than those in the **input**" (Ibid).

3400

SYSTEM (Self-energizing)²⁾

A system which possess sufficient stored **energy** to be able to draw on its **reserves** to react to some external **stimulus**.

G. BATESON gives the following examples: "If I kick a dog, his immediately sequential **behavior** is energized by his **metabolism**, not by my kick. Similarly, when one neuron fires another, or an impulse from a microphone activates a **circuit**, the **sequent event** has its own **energy sources**" (1973, p.379).

However, as stated by BATESON: "Of course, everything that happens is still within the limits defined by the law of **energy** conservation" but "... in general, in the systems with which we deal, the **energy** supplies are large compared with the demands upon them; and, long before the supplies are exhausted, 'economic' limitations are imposed by the finite number of available alternatives... A telephone exchange at a time of emergency may be 'jammed' when a large fraction of its alternative pathways are busy. There is, then, a low probability of any given **message** getting through" (Ibid).

A **complex system** has generally "... the necessary **circuit structure** so that (its) **energy** expenditure can be an inverse **function** of **energy input**" (Ibid., p.457).

Such a system, when its **energy reserves** are lowering, will generally redirect their use to replenish them.

This was the general idea of W. GREY WALTER's electronic tortoises.(1955).

3401

SYSTEM (Self-modifying)^{1) - 2)}

A system able to generate new **interrelations** between its internal **processes**.

According to G. KAMPIS, who introduces this notion, the general conditions of existence of the system are modified by its own **activity**. As a result the system must readapt itself in order

to survive. This entails the shaping of new **interrelations** between **processes** and may lead to a deep **transformation** of the system (1989, p.87-98).

Contemporary complex **human systems** seem to be self-modifying, which may explain that they become ever more difficult to manage.

Self-modification seems to be a later stage of **self-organization**, but its status in relation to **autopoiesis** is not yet quite clear. Self-modification does not seem compatible with M. ELGEN's **hypercycle**, for instance.

3402

SYSTEM (Self-organizing)²⁾

I. A system that construct itself by joining **parts** formerly separated.

This is the transit from no-organization to organization.

This meaning, according to W.R. ASHBY, who proposed it (see 1981, p.58), is "simple and unobjectionable". It possibly looks simple because we see it at work so frequently. However the **initial conditions**, **causes** and ways of the shaping of specific **links** and **interactions** among the newly connecting **elements** in this **autogenesis process** still remain relatively obscure.

Thereafter, still in ASHBY's words the system changes "from a bad organization to a good one". "*Bad*" seems unluckily valorative. In any case, the system must first of all come into existence, a **process** now quite well explained by V. CSANYI's **models** of the **zero system** and its **autogenic precursors** (1989, 1993). It can then change from a simpler to a more **complex** type of **organization**, or from one type to another one, in accordance with varying internal or external conditions. This lead us to the second definition.

2. "A system able, with no explicit outside help, of improving its **performance** while pursuing its **goals**" (Adapted from G. KLIR, 1991, p.156).

This is obtained by modifying (see preceding entry) the organization of the **interactions** between the **elements** of the system.

This kind of **processes** has been investigated by H. HAKEN (**synergetics**) and also through the study of **networks** progressing toward a more ordered organization. Self-organization is also closely related to the **emergence** of **autopoiesis**, because an already existing system is "**organizationally closed**" and thus able to modify its internal **structures** and **processes** only within very narrow **limits**. This is the case for ex., of any **living system**.

Finally, giant **fluctuations in dissipative systems far-from-equilibrium** (I. PRIGOGINE et al.) may be conducive to the **emergence** of a higher **level** of organization, a **process** also possibly more related to **autogenesis** than to self-organization.

3403

SYSTEM (Self-referential)

John MINGERS proposes the following classification of self-referential systems (1999, p. 28)

3404

SYSTEM (Self-referential)²⁾

"A system that changes the **states** of its **components** in a **operationally closed way**" (P.M. HEJL, 1992, p.115).

HEJL states the following consequences:

- Self-maintaining systems are necessarily self-referential;
- However, not all self-referential systems are self-maintaining (Ibid).

HEJL gives as an example of this last case, the **brain**, which could not be self-referential if it was not maintained by the whole biological system.

This neatly shows the difference between **independence** (inexistent), and **autonomy** in **autopoietic systems**.

3405

SYSTEM (Self-reproducing)²⁾

This is now such an ambiguous expression that no reliable definition seems possible. At least five different meanings can be identified. Self-reproduction could be said to occur in:

1. the division of a **cell**, transmitting its genetic material without modification to the resulting new **cells**;
2. the production by cloning of new plants also genetically identical to the original one;
3. the production of new plants only by vegetative propagation, as for example by rhizomes in **colonies** of poplars, or stolons in strawberry plants;

These first three **meanings** are relative to **concrete living systems**.

From an abstract **viewpoint**, we may distinguish:

4. the self-reproductive **automaton**, as for example in some cases in J. CONWAY's **Games of Life**;
5. the **autopoietic** reproduction of a system through which the system more or less continuously reconstructs itself by the **cyclical** or **recursive** reproduction of its **elements** and the characteristic **links** amongst them.

These different **meanings** are obviously related. Remains to be seen if the two last ones can be compatibilized, really becoming general **models** for the former ones, and how.

3406

SYSTEM (Source)^{2) - 3)}

"A **set of variables**... established as a result of our **interaction** with an **object** of interest" (G. KLIR, 1993, p.41).

This definition corresponds to **reconstructability analysis**.

Source systems can be viewed "as sources of empirical **data** regarding specific **attributes** of the investigated **object**" (KLIR, 1991, p.221).

KLIR writes: "The most primitive epistemological **category** consist solely of a *experimental frame*, a **set of variables**, their **state sets** with appropriate **observation channels**, **time** (as a **parameter** within which the **variables** are observed), and an appropriately defined **time set**. The term *source systems* is usually used for systems defined at this **level** to indicate that such systems are, at least potentially, sources of empirical **data**. Systems on different higher **epistemological levels** are distinguished from each other by the **level of knowledge** regarding the **variables** of the associated source system" (1988, p.151).

KLIR makes also an important observation: "Since we deal with systems distinguished on **objects** and not with the **objects** themselves (in their totality), it is not operationally meaningful to view **complexity** as an intrinsic property of **objects**. While complexities of **objects** may exist in the **ontological** sense, they are **epistemologically** and **methodologically** vacuous, in contrast to **complexities** of systems" (1993, p.41).

This reminds us of "the map, which is not the territory".

→ "ontological skepticism".

A zoologist, for instance, would observe different characteristics and **variables** in order to study a variety, a species or a family of animals.

The source system concept seems quite close to J.G. MILLER's "**concrete system**". It surges from something "out there" that we observe in a defined way for some defined **purpose**.

3407

SYSTEM (Stable)^{1) - 2)}

"...(a system that) has the property that if displaced from a state of **equilibrium** and released, the subsequent movement is so matched to the initial displacement that the system is brought back to the **state of equilibrium**" (W.R. ASHBY, 1960, p.54).

Such property could be considered as a generalization of the **Principle of LE CHATELIER**.

ASHBY emits a series of interesting comments related to the properties of the stable system.

He writes: "A **variety of disturbances** will therefore evoke a **variety** of matched reactions"... and "... the **behavior** of a stable system may be described as **goal seeking**" (Ibid).

Furthermore "An important feature of a system's **stability** (or **instability**) is that *it is a property of the whole system and can be assigned to no part of it.*"

Or, in other words: "*The stability belongs only to the combination; it cannot be related to the parts considered separately*" (Ibid, p.56).

This implies that no change can be introduced in some specific **part** of the system without triggering some side effects and, possibly a complete reordering of the **whole** system, or even its destruction.

ASHBY expresses the same idea as follows: "In a stable system the effect of fixing a **variable** may be to render the remainder unstable"... and "... *the presence of stability always implies some coordination of the actions between the parts*".

The stable system, as a **model**, corresponds also to PRIGOGINE's concept of the **thermodynamic system near of its point of equilibrium**, i.e. not submitted to giant **fluctuations** that could transform it radically or destroy it.

Stable systems are also called "**Equilibrium Systems**", in opposition to **critical systems**. P. BAK expresses their **stability** condition as follows: "... under very restrictive conditions, **equilibrium systems** can exhibit **scale-free behavior**" (1996, p.35). This seems to be equivalent to PRIGOGINE's concept stated in his **theorem of minimum entropy production**.

3408

SYSTEM (State-determined)²⁾

A system whose **path** is uniquely determined, regardless of how the system arrived at the given initial **state** (After HALL & FAGEN, 1956, p.25).

W.R. ASHBY thus explains the concept: "The **field** of a state-determined system has a characteristic property: through no point does more than one **line of behavior** run" (1960, p.27).

Or, "A finite **set of variables** for which, at any instant, the **state transition** is completely determined by the present **state**" (Ibid).

In other words, in a state-determined system, there are no **bifurcations** because there does not exist any **indetermination** in any **line of behavior**: the system is wholly **deterministic**.

ASHBY observes that: "Because of its importance, science searches persistently for the state-determined" (Ibid, p.28).

He could have added that contemporary science, after running into many dead ends, is starting in earnest to research non absolutely **deterministic** systems, whether **non-linear**, **far-from-equilibrium**, or **chaotic**. See for example R. ROSEN's paper on "The Physics of **Complexity**" (1991 c, p.493- 500).

3409

SYSTEM (State-maintaining)²⁾

According to R.L. ACKOFF, a system is state-maintaining if:

"1) it can react in only one way to any one external or internal **event** but

"2) it reacts differently to different external or internal **events**, and,

"3) these different reactions produce the same external or internal state" (1972, p.85).

The following comment by this author seems to show that self-maintenance is different from **organizational closure**: "Such a system only reacts to **changes**; it cannot respond because what it does is completely determined by the causing **event**. Nevertheless it can be said to have the *function* of maintaining the state it produces because it can produce this state in different ways under different conditions" (Ibid).

3410

SYSTEM (State-transition)^{2) - 3)}

"A *state-transition system* is defined in terms of a **set** of overall **states** based upon a particular **mask** and a specification of conditions for transitions between these **states**" (G. KLIR, 1988, p.151).

It is thus a collection of **data**, not yet conceptually organized, except as a result of the characteristics of the selected **observation** device, and, obviously, of the **purpose** which oriented this **selection**.

Accordingly, a systemic **model** cannot be constructed without the introduction of some supplementary conjectures about the global signification of the **data**.

3411

SYSTEM (Static)^{2) - 3)}

A system "to which no **events** occur" (R.L. ACKOFF, 1972, p.84).

R.L. ACKOFF gives the example of a table "... a static **concrete system** consisting of four legs, top screws, glue, and so on. Relative to most research purposes it displays no **change** of structural properties, no change of state" (Ibid).

This is of course a situation defined by the **observer's purpose**. There are always **dynamic** aspects in any system, even if, for some reasons, they are not taken in account in some cases.

Obviously, when considered from a static **viewpoint**, a system is not very interesting.

3412

SYSTEM (Stationary)²⁾

"A system which is in dynamic or statistical **equilibrium**" (G. PASK, 1961a, p.115).

PASK explains: "Its statistical characteristics do not change. In a non-stationary system the statistical characteristics do change" (Ibid).

3413

SYSTEM (Steady state)²⁾

A system that maintains a more or less general **constancy** of its main **processes** and **variables** throughout **time**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

A steady state system should not be confused with a static system. No static system could ever process anything, nor survive any disturbance.

Steady state systems are **dynamically stable**.

→ **Homeostasis; Steady state**

3414

SYSTEM (Stellar type)

→ **Stellar type System.**

3415

SYSTEM (Structure)^{2) - 3)}

"One overall system that integrates several systems that share some **variables** or interact in some other way" (Adapted from G. KLIR, 1991, p.58).

Or "a set of interacting **behavior** or **state-transition systems**" (KLIR, 1988, p.151).

KLIR adds: "The **subsystems** forming a structure system are often called its **elements**. When **elements** of structure systems are themselves structure systems, we call the overall system a **second-order structure system**. Higher-order structure systems are defined recursively in the same way... Different **categories** of structure systems are thus distinguished by their **orders** and by the type of their ultimate **elements**" (1991, p.58).

KLIR also shows how structure systems can be conveniently represented by block diagrams (p.59), and how the ordering of epistemological systems **categories** can be described by semi-lattices (p.69).

Connecting the behavioral and state-transitional aspects of the system, KLIR reaches the epistemologically highest **level** in the **hierarchy** of inquiring **methods** that he proposed, in relation to his **reconstructability analysis**.

It is clear that he understands "structure" as a **set** of **diachronic** and interconnected **transformations**.

3416

SYSTEM (Symbolic)^{2) - 3)}

"A **concrete system** some of the **components** of which represent other **objects**" (M. BUNGE, 1993, p.212).

BUNGE gives **languages** as examples of symbolic systems. He extends however the definition as to cover: "... books, tapes, diskettes, blueprints, maquettes, toys, etc. On the other hand a stray **symbol**, such as a road **sign**, is not a system, though it may eventually become the founder of a symbolic system" (Ibid).

3417

SYSTEM (Teleogenic)^{1) - 2)}

"A system capable to generate its own **goals**" (N.A. COULTER Jr., 1968, p.35).

COULTER, Jr. gives the **brain** as an example: "A **brain**... has been designed by **evolution** to survive in an uncertain and sometimes hostile **environment**. In contrast to a computer, a **brain** is a teleogenic system... While under some conditions a **brain** may be controlled by outside **goals** or forces, it necessarily includes a self-determined **component**" (Ibid).

This was written in 1968, when the more precise concept of **organizational closure** of the **whole** (and not merely the self-determined **component**) was not yet well known.

3418

SYSTEM (Trivial)²⁾

A system whose **behavior** does not change significantly in **time**.

Its behavior is thus highly predictable.

Such a system is not learning by **experience** and is generally submitted to tight **controls**.

Most simple man-made systems were **trivial**, being submitted to also simple **regulators** or **controls**. New man-made systems tend however now to become **non-trivial** through the introduction of **meta-controls** and/or **learning** devices, as for ex. back- **propagation** in complex controlling **networks**.

→ **Artificial life; Network (Parallel processing); Parallel Distributed Processing; Trivialization**

3419

SYSTEM (Ultrastable)²⁾

W. R. ASHBY thus describes the ultrastable systems **behavior**: "(it) acts selectively towards the **fields** of the main **variables**, rejecting those that lead the representative point to a **critical state** but retaining those that do not" (1958, p.91).

In other words, the ultrastable system remains within the **limits** of a **basin** or **vicinity** defined by a stable attractor.

3420

SYSTEM (Viable)^{1) - 2) - 4)}

A system capable to maintain its independent existence (Adapted from St. BEER, 1989, p.11).

The Viable System Model has been introduced by S. BEER from 1966 on. At that time he wrote:

"Viable systems have the ability to make a **response** to a **stimulus** which was not included in the list of anticipated **stimuli** when the system was designed. They can learn from repeated experience what is the optimal **response** to that **stimulus**. Viable systems grow. They renew themselves... They are robust against internal **breakdown** and **error**. Above all, they continuously adapt to a changing **environment**, and by this means survive – quite possible in conditions which had not been entirely foreseen by their designer.

"Now the systems that must be handled in the economic, social and industrial worlds are indeed systems of such viable characteristics, which tend to have (when they are successful) the properties just listed. Cybernetics has demonstrated that they have these properties *only if* they have high **complexity**; they must exist beyond a certain '**complexity barrier**' to be viable" (1966, p.256).

BEER progressively developed the complex cybernetics involved in the Viable System Model. Hereafter a very condensed summary of the VSM. However, no summary can satisfactorily resume this complex work. For a full development, see "The Heart of Enterprise" (1979).

A Viable System is made of five types of interconnected systems at different **levels**.

"**Systems One**" are frequently numerous in a **complex system**. Each one attends a specific **process** related to a specific part of the active **environment** of the system.

"**Systems Two**" are coordinating **metasystems** of Systems One, which have anti-**oscillatory effects**, or act as "**input attenuators**", locally and globally (p.176-7).

"**Systems Three**" are concerned with the general **coordination** and **coherence** between Systems One and Two (p.205-7).

"**System Four**" responds to the need to cope with a larger **environment** and an unknown future. It aims at giving a wider **space (environment)** and **time (planning) frame** to Systems Three to One. To operate correctly any System Four needs to have access to the full **variety** available in Systems One to Three (p.349).

"**System Five**", in accordance with ASHBY's **Law of Requisite Variety**, must contain general **models** of Systems Three and Four in order to be able to **control** through general **closure**, if possible, unexpected external **variety** (p.352).

Unfortunately, System Five, as a "general boss" (individual or collective) is always in danger to become an autocratic power, "that will soon or later make a global mistake". (A possible way to avoid this could be the **heterarchical organizational model**).

While basically a model for the practical uses of **management**, the VS Model represents the **operation** of complex systems in general.

BEER's VSM relies heavily on two very basic cybernetic concepts: ASHBY's **variety** and MATURANA and VARELA's **organizational closure**.

Also unfortunately, the VS Model seems to be very difficult to assimilate for people who lack at least a global **understanding** of evolved cybernetic concepts, i. e. not merely WIENER's "**Communication and control**", or not even these! This leads easily to an "implementation syndrome" (p.442-3).

3421

SYSTEM (World) ⁴⁾

"The human supersociety composed of all the human societies" (M. BUNGE, 1993, p.213).

M. BUNGE makes the following suggestive comment: "The world social system was born on October 12, 1492. By the 18th century it was in full economic swing. By the time of World War I, it had also become a political system, albeit not a cohesive one. World-wide integration is still in the making" (Ibid).

It may be viewed as a **network** in course of creating myriads of new **interaction links**, possibly on its way to become a planetary **autopoietic system**. But there is a rock-bottom necessity: to become integrated within the planetary **environment** as a **whole**.

→ **Spaceship Earth**

3422

SYSTEM DESIGN ^{1) - 4)}

Any **method** aiming "at the construction of a **model** or a "blueprint" of a system to be developed" (B. BANATHY, 1973, p.89).

J.van GIGCH states: "The creation of any **artifact** requires a deliberate thinking **process** which is called *design*. It involves three main components: 1) the appraisal of *reality*, 2) *modelling* and 3) *metamodeling*" (1992, p.1).

According to BANATHY, who promotes the **concept**, systems design "aims at the construction of a **model** or a "blueprint" of a system to be developed" (1960, p. 89).

Such a design should be co-participative among all the interested people. It progresses through exploration of the possibilities, the search for innovations and a constant search for renewed **consensus**.

One of the most difficult aspects of system design is the search for and the discovery of hidden or ignored aspects of the situation which motivates the design. (see "**invisibility**").

Another is the dubious character of any **long-term forecasting**, due to the natural **turbulence** of any **environment**, which leads easily to **chaotic** conditions.

BANATHY himself states that "System development involves the formulation, testing, revision and validation of the system" (Ibid) (i.e., the blueprint and the system itself during its build-up).

→ "**Design (Systems)**" and "**Design (Systems Approach to)**".

3423

SYSTEM ENTITY STRUCTURE ^{2) - 5)}

A taxonomic **structure** employed to classify the various possible ways to modelize **complex systems**.

The "System Entity Structure" has been introduced by B. ZEIGLER (1984 and 1994).

In H. PRAEHOFFER's words: "The system entity structure is used to manage a family of **models** and has to support the **representation** of **decomposition**, **couplings** and **taxonomy**. **Decomposition** is used to represent the way real systems are composed into **components** in a **hierarchical** manner. **Coupling** specifications define how these **components** can be coupled together. Taxonomic **knowledge** means the **representation** of different kind of **objects** (i.e. how they are **categorized** and subclassified)" (1991, p.301).

This is a good **methodological** track, well adapted to conventional **computers** and based on the classical view of systems as pre-ordained **hierarchies** of **components**. The key word is here obviously "**decomposition**", with its somewhat **reductionist** overtones. But what about **networks** **representation** of **parallel learning** systems?

ZEIGLER defines the structure as a labeled **tree**, in accordance with the following axioms (as resumed by PRAEHOFFER):

"1. **Uniformity**: Any two **nodes** that have the same name have identical attached **variable** types and **isomorphic subtrees**

"2. **Strict hierarchy**: No **label** appears more than once down any **path** of the **tree**

"3. **Alternating mode**: Each **node** has a **mode** that is either entity, aspect, or specialization; if the **mode** of a **node** is entity, than the **modes** of its successors are aspects or specialization; if the **mode** of a **node** is aspect or specialization, then the **modes** of its successors are entity. The **mode** of the root is entity.

"4. **Valid brothers**: No two brothers have the same **label**

"5. **Attached variables**: No two **variable** types attached to the same item have the same name.

"6. **Inheritance**: Every entity in a specialization inherits all the **variables**, aspects, and specializations from the parent of the specialization...

"The best way to represent an entity **structure** is by a pictorial **representation** of the **tree structure**. The **nodes** of the **tree** represent entities, aspects and specializations. The **arcs** of the **tree** represent the relations between parents and their children. As, depending on the type of the **node**, we can identify different relations between the **nodes**, we use different **arcs** to represent these relations. An aspect relation is depicted by a single **line**, a multiple **decomposition** relation by three parallel **lines** and a specialization relation by a double **line arrow**" (Ibid., p.302-303).

It would be of much interest to evaluate FORRESTER's **systems dynamics models**, and other types of formalized **models** in the light of ZEIGLER's **methodology**.

Another good subject for research should be the **constraints** imposed by the nature of **digital** sequential **computer** on the **methodologies** of **complex systems modelization**.

For **graph** terminology, as used here, see "**graph**" and "**graph theory**".

3424

SYSTEM SPACE ^{1) - 2)}

"... the **domain** that the system occupies as defined by its **boundaries**" (B. BANATHY, 1973, p.89).

It should possibly be advisable to speak about the system **space-time**, in order to convey better the idea that the system is by necessity a **dynamic** entity. Furthermore, through **time**, the system space may well expand or contract.

3425

SYSTEMATICS (Evolutive) ²⁾

A general **taxonomy** of living **organisms** (Derived from LINNAEUS's "Systema Naturae" by later evolutionists).

Of course, "systematics" is to be clearly distinguished from "**systemics**", while a systemic concept pervades any **classification** by reference to **form** and **function**.

The evolutive **paradigm** historically confirmed the extension of systematics to fossils and gave it a **time** dimension which was lacking in LINNAEUS work.

Nowadays, many biologists adhere to other types of **taxonomies**, as a result of the difficulties of **consensus** on **criteria** of **classification** of **complex systems**: that which is readily observable is not necessarily fundamental.

→ **Cladistic analysis**; **Classification**; **Cluster**

3426

"SYSTÈME GÉNÉRAL" (Diagram of the) ²⁾

J.L.LE MOIGNE proposes a general **model** of system, which he calls "Système Général" and whose diagram he characterizes as follows:

"...An **object**, in an **environment**, endowed with **finalities**, which engages in an **activity** and whose internal **structure** undergoes an **evolution** through **time**, without however to loose its unique **identity**:

"In a more trivial way, but possibly easier to remember:

- *something* (anything that can be identified)
- which *do* something (**activity** = **function**)
- and which, endowed with a *structure*
- *evolves* in **time**
- *within* something (**environment**)
- *for* some reason (**finality**)

or, yet:

- an object active within an **environment** structured in relation to some evolving **finalities**" (1977, p.37).

We should however take time to reflect seriously about the meaning of terms like **structure** or **finality**. It would also probably be better to avoid the term **evolve** and speak of **adaptive transformations** for the systems which maintain their **identity**.

3427

"SYSTÈME GÉNÉRAL" (Structural matrix of the)²⁾

According to J.L. LE MOIGNE, the "Système Général" model is "a **net** marked off an **environment**". (The **net** is made of interconnected **processors**).

These interconnections are specified, and can thus be represented by a **matrix**, which reproduces the global **structure** of the system. It is also possible to figure it by a **graph**, in which the internal **processors** of the system are enclosed within a **boundary**, even if some of them are connected with external **sources** from which the system obtains its **inputs**, or with external **sinks** which receives its **outputs**.

This **model** should be compared with J.G. MILLER's one (1978), with G. KLIR's one (1990) and with those of J. FORRESTER (1961)

3428

"SYSTÈME GÉNÉRAL" (Theory of the) (J.L. LE MOIGNE)^{1) - 2) - 3)}

J.L. LE MOIGNE states unequivocally that, in his opinion: "The theory of 'the' General System is the theory of **modelization** of the **objects** (natural or artificial, complicated or complex) by way of this artificial **object** slowly shaped by the human mind, that L. von BERTALANFFY did propose to call the General System: a system which is a **model** of a general nature".

LE MOIGNE adds: "This artificial **object** is apt to be defined: it is possible to endow it with properties, it is possible to verify the **coherence** of these properties, it is possible, finally to use it in order to represent... other **objects**" (1977, p.36).

In J.C. LUGAN words: "This 'système général' integrates in a formal way a conjunctive axiomatics" (1993, p.92) (as opposed to the disjunctive one expressed by the **separability axiom**). It establishes a general formalism for the modelization of complex **phenomena**.

While this concept is, for sure, quite useful, it is very different of what "numerous anglo-saxons authors understand as "General System(s) Theory" – which may be translated in French by "Théorie Générale des Systèmes" and which gathers by progressive aggregation a great number of concepts and **models** related to **complex systems** (and, more recently to those systems called **composite** in this work).

3429

SYSTEMIC METHODOLOGY for STRATEGIC MANAGEMENT (SM: SM)⁴⁾

This methodology is proposed by R. RODRIGUEZ ULLOA, (Instituto Andino de Sistemas, Lima, PERU), in the following terms:

"Briefly, SM:SM is composed by five modules:

"a. The Efficacy and **Efficiency** Criteria System (EECS): Which defines, sets and considers efficacy and **efficiency criteria** under which all the **strategic change** will be monitored and controlled

"b. The Providing **Resources** System (PRS): Which obtains and provides for all kinds of **resources** to the **problem-solving** system at any time...

"c. The Social Research System (SRS): Aimed at detecting an **organization's** strengths and weaknesses

"d. The Organizational Policy Proposal System (OPPS): Oriented to define the present and future **organizational** mission and the **paths** (**strategies**), **means** (**resources**), timing and **management** style to achieve global **strategic change**

"e. The Implementation Organizational Policy System (IOPS): Aimed to disseminate, motivate, execute, supervise and control the global **strategic transformation process**" (1993, p.235).

SM:SM is actually used in **development** projects in Peru.

3430

SYSTEMIC PROPERTIES: a tentative listing¹⁾

- A **whole** is more than the sum of its **parts** (it includes the **interactions** of the **parts** and their possible multi-functionality)
- A **part** may have different **action potentials** in different systems (H in NH₄, or in HCl).
- A reliable system can sometimes be made of unreliable, but interacting parts (von NEUMANN)
- A **whole** tends to maintain a specific and a **dynamic stability** in **time**, by being adaptive.
- In a **whole**, internal **relationships** are frequently organized in **networks**.
- Internal **networks** are dynamic and adaptive through multiple **simultaneous** and repeated **feedbacks**.
- **Adaptiveness** remains constrained within defined **limits**, frequently in a cyclical way (**limit cycles**).
- A **whole** is autonomous in relation to its specific **environment**, i.e. is able to determine within **limits** its **relationships** with it (for ex. Internal temperature **regulation** in mammals; or **Inputs** and **outputs flows** in an enterprise).

- A **whole** can associate with others and build **wholes** of higher **complexity** (Fusions between enterprises, the European Union)

Generally speaking, systemic properties conform a set of correlated **explanations**, useful to describe integrate **behavior** in **entities** and **issues** made of numerous interacting **elements**, as contrasted, but also complementary to the more classical **analytic approach**.

3431

SYSTEMIC RISK¹⁾

Any risk which specifically results of the **complexity** of a system.

The specific risk is an ever possible consequence of some unadverted **instability** within the system, due to some architecture error if man-constructed, or more exceptionally of some inherent property in a natural system.

Man-constructed systems, when complex, are very difficult to fully understand and to manage properly. Furthermore, they are generally more or less unstable (submitted to **chaotic determinism**).

Natural systems may contain unknown **long-term instabilities**, as for example in the case of geological faults activity.

In **human systems** a supplementary factor of risk is the ever latent possibility of operative or **management** errors that may trigger a catastrophic course.

3432

SYSTEMIC THINKING^{1) - 3)}

A general approach to scientific inquiry that is specially interested in the study of **complex situations** and **systems**, using specific concepts and **models**.

Back in 1941, A. ANGYAL was already comparing the causal way of thinking with the systemic one, in the following terms: "In causal research, the task is to single out from a multiplicity of **data**, pairs of **facts** between which there is a necessary **connection**. In systems thinking the task is not to find direct relations between members but to find the **superordinate system** in which they are connected or to define the **positional value** of members relative to the **superordinate system**" (1941, p.24).

He added: "One thing... seems clear, namely that systems cannot be deduced from **relations**, while the deduction of **relations** from systems still remains a possibility. If that is the case then the more general logical genus would be 'system', while 'relation' would be a reduced, simplified system which is adequate only for the logical presentation of very simple specialized constellations" (Ibid., p.25).

This viewpoint seems however somehow contradictory with the concepts and **methods** of KLIR's **reconstructability analysis**. The ideas which seem to be lacking here are those about *relations between relations* and *relations inbetween levels*.

From a different viewpoint, M. BUNGE writes: "Some systems theorists believe that **systemics** belongs in mathematics. I submit that this opinion is mistaken, because, unlike pure mathematics, **systemics** is about real things. (**Systemics** has a mathematical formalism but a factual content). Others seem to believe that **systemics** is a mushy popular philosophy, rehashed romantic talk about unanalyzable **wholes**. This opinion too is mistaken, because **systemics**, unlike **holism**, analyzes systems, and furthermore it does so with the help of mathematics – a *bête noire* of all romantics" (1979, p.221).

It should be observed however that systemics uses evermore new mathematical tools of, at least, a partially qualitative character.

3433

SYSTEMIC/Holistic versus NONSYSTEMIC THINKING¹⁾³⁾⁴⁾

M. MULEJ and his colleagues and collaborators at the Faculty of Economics, University of Maribor, Slovenia, resume in the following listing the characteristic differences between these two ways of thinking (2002)

Systems/Systemic/Holistic Thinking	Unsystemic, Traditional Thinking
Interdependence/s, Relation/s, Openness, Interconnectedness	Independence, Dependence, Closeness
Complexity (plus Simplicity, or complicatedness)	Complicatedness
Attractor/s	No influential force/s, but isolation
Emergence	No process of making new attributes
Synergy, System, Synthesis	No new attributes resulting from relations between elements
Whole, holism, big picture	Parts and partial picture attributes only

They proceed by describing the **attributes** of the various terms and expressions used (all of these in this Encyclopedia)

The authors also underline that systems thinking is different and in some sense wider than **systems theory** (or theories), which is "an abstract generalization of the practical attributes of systems thinking, or a **description** of complex **entities** called systems" (Ibid)

The paper includes also some historical information and concludes that "systems thinking based on a **realistic** systems theory may be

able to help humankind find a new way toward **survival**".

3434

SYSTEMICS^{1) – 3)}

An open **set** of concepts, **models** and practical tools useful for a better **understanding** and eventual **management** of complex **situations** or entities of any type.

It would seemingly be advisable to replace expressions like "**Systems Research**", "**General Systems Theory**", "**General Theory of Systems**", or "**Systems Science(s)**" by the word "**Systemics**". In this way many **ambiguities**, sterile controversies and in some cases, inflated claims could probably be laid to rest.

According to M. BUNGE: "Because of its generality it has a sizable overlap with **ontology** and metaphysics construed in the traditional pre-Hegelian sense, as well as in our own sense of scientific **ontology**. Both systems experts and ontologists are interested in the properties common to all systems irrespective of their particular constitution, and both are intrigued by the peculiarities of extremely general theories, which are methodologically quite different from specific theories" (1979, p.3).

Generally speaking, systemic **models** "have sought to restaure multidimensionality to our world views and **modes of inquiry** (M. DODDS and G. JAROS, 1994, p.9).

Furthermore, systemics, combined with cybernetics, has introduced new concepts and **models** of **nonlinear** complex **processes**, as for example **catastrophes**, **deterministic chaos**, **dynamic stability**, **dissipative structuration**, **feedbacks**, etc.

A more specific aim of systemics is stated by H. PRAEHOFFER: "... an **interdisciplinary** discipline that tries to provide general concepts for **model building** and **problem solving**" (1991, p.290).

As noted by M. BUNGE: "Systemics has two related motivations, one **cognitive** and one practical" (quoted by M.C.LE DUC, 1992, p.916).

N. PEGUIRON observes: "Systemics appeared – one could say – progressively, as a reply to a new awareness of a varied mixture of discoveries:

- **indeterminism** in classical mechanics.
- the incapacity, in spite of an even deeper **knowledge** in the classical senses, to explain in pluricellular living beings, the **phenotype**, starting from the **genotype**.
- a great difficulty in modeling complex **evolution** in **ecology**, and also the discovery of the limited character of that **ecosystem** which sustains human **activity**.

"On the scientific level, systemics appeared as a result of some new disciplines, which it assembled in a study of those matters that science could not yet explain" (1989, p.6)

Among these new disciplines or theories, PEGUIRON cites:

- **Thermodynamics of irreversible systems** out of **equilibrium**.
- **Catastrophe theory**.
- The concepts of **strange attractors** and **chaos**.
- The theory of **fractals**.
- We may add, among others:
 - at least three different **understandings** of what is **autonomy** (BERNARD/CANNON/VEDRYES; ASHBY; MATURANA/VARELA)
 - the concept of **autopoiesis**
 - new ideas about **cycles** and **cyclical behavior**
 - the **cybernetics** of **feedback**, **regulation**, **control**, **variety** and **constraints**
 - the theory of the **observer**
 - some consequences of **relativity (simultaneity in different referentials)**.

This "toolbox" of conceptual **models** is becoming ever more useful for the study of all kinds of **complex systems** in neurology and **brain studies**, **information** and **communication** sciences, behavioral sciences, **ecology**, economy, social sciences, **management**, etc...

All of the listed notions are related, not to out-of-context phenomena but on the contrary to interconnected ones, generally within complex specific settings and constrained by not necessarily **stable** conditions. Accordingly, systemics abandons the "... *et ceteris paribus*" clause.

The global goal of systemics is thus defined by J.C. LUGAN: "(Systemics should) replace the disjunction-reduction paradigm by a **distinction-conjunction** one, which should allow **distinction** without disjunction and **association** without identification or **reduction**" (1993, p.113).

It should be stressed that systemics is not merely a **systematics** of ideas, as for example some philosophical "systems" of ideas. While Cl. BERNARD said that "Systems are not in nature, but in men's heads", it should be understood that they reflect somehow reality. Here is the basic clivage between systemic **understanding** of **behavior** and **structure** of "something out there" or rigid and systematic **models** created once and for all by a self-limiting **mind**. There is nothing wrong with systematics, but it refers to **taxonomics**, **classification** and highly abstract **constructs**, quite disconnected from anything concrete.

On the contrary, systemics cannot be reduced to a more or less limited compendium of cognitive recipes and their products.

M.C.LE DUC is probably right saying that "... **constructivism** emphasises the **process** of working back and forth between our mental world and the concrete world". Consequently, he proposes the following axioms for systemics:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"1. There is a *concrete world* around us that is accessible to our *mental world* only by the mental **structures** already in the mental world.

"2. New mental **structures** are **constructed** from existing ones to enhance the *fit* between the mental world and the concrete world (PIA-GET)

"3. Mental **structures** are organized into **levels**, some of which have **emergent** properties" (1992, p.917).

For interesting historical data and philosophical comments, see also R. RODRIGUEZ DELGADO (Chap.2 and 3) (1997)

→ "**Structural differential**".

3435

SYSTEMICS in Latin America ¹⁾

There are two systems societies in constant activity in Latin America: one is the **Argentine Association for General Systems Theory and Cybernetics** (also known as GESI (Group for the Study of Integrated Systems) active since 1976. The other is the **Instituto Andino de Sistemas** in Perú, created in the 1980's (see the corresponding entries)

There are however other informal groups, which produce original work. In Argentina Prof. Enrique HERRSCHER created in 2001 the Center for Systemic Action and Thinking (CAPSIS in Spanish abbreviation), in collaboration with ACKOFF's Interact Institute. CAPSIS organizes research, teaching, events, and cooperates with various systems associations. Herrscher and collaborators published a book in Spanish: "Pensamiento Sistémico" in 2003. (see bibliography)

At the Universidad de los Andes, in Mérida, Venezuela, Prof. H. LOPEZ GARAY and R. FUENMAYOR elaborated what they call **Interpretive Systemology**.

Another group is at the Technological Institute of Monterrey, Mexico, where Prof. R. CARDENAS forwarded **Generic Design** after her collaboration with Prof. John WARFIELD.

In São Paulo University, Brazil, another team, under the leadership of Prof. Dante MARTINELLI, developed a School of **Management** in systemic terms.

And even if they worked for many years in North America and Europe, it should not be ignored that Humberto MATURANA and Francisco VARELA were as Chileans, the founders of the so-called **Santiago Theory** (being Santiago de Chile, the name of the Chilean capital)

Other scholars in Chile, Mexico, Colombia and Venezuela have also produced interesting work.

It is even quite possible that some Latin American scholars in the field are still unknown to this editor, considering the quite imperfectly developed scientific communications in this

huge and geographically very fractured continent, and some lack of practical operativeness of the Asociación Latinoamericana de Sistemas (ALAS), because of very scant funding.

3436

SYSTEMICS in Switzerland ¹⁾

There are two main centers in Switzerland where systemic and cybernetic **concepts** and **models** have received a sustained attention and generated original work of great interest.

The first one is the School of Business Management at the University of Sankt Gallen. During the 1970's and 1980's, Prof. Hans ULRICH and Gilbert PROBST developed original ideas about **self-organization** as a way for the **management of social systems**. They also insisted on the necessity of global views for managers confronted with organizational **issues** and **decision making**.

More recently, Prof. Werner ULRICH has consistently explored issues in **social design** and **planning**. He developed what he calls "Critical heuristics" as a tool to be used in this field.

Prof. Markus SCHWANINGER explored in recent years the possibility and characteristics of intelligent organizations and the conditions for integrated business enterprises planning, specially **competence in understanding** and managing **complex issues**. He sees a kind of ecological dimension in organizational intelligence.

The other center much interested in systemics is in the French speaking part of the country. A quite significant work is constantly forwarded at the Association F. Gonseth, Institute de la Méthode in Bienne. (F. Gonseth has been an outstanding Swiss epistemologist of the 20th C. who introduced the concept of "**ideoneity**"). Consequently the attention of this group is centered on more abstract themes as for example: **representation**, the mind-body problem, **phenomenology**, **complexity**, **transdisciplinarity**, **perception**, **autonomy**, **constructivism**, **holism**, conceptual a priori, **truth** and **idoneity**, Popperian critical rationalism, **autopoiesis**, etc.

The Group organizes "written symposia" in which these themes are however discussed in a kind of conversational style. The debates are published in a periodic bulletin since more than 20 years and also in the "Cahiers de l'Institut de la Méthode". Among the most active participants are J.C. TABARY, a neuropsychiatrist; F. BONSACK prof. of philosophy, P.M. POUGET, prof. of philosophy, J.F. QUILICI-PACAUD, technologist, M.C. DUPRE, anthropologist.

Another participant is Prof. Eric SCHWARZ, of the Neuchâtel University. He is an active organizer of meetings and tutorials in Neuchâtel and Geneva, and a frequent author of papers centered in holism, **evolution** and other wide-embracing themes in cybernetic and systemic

terms. He created the "Centre Interfacultaire d'Etudes Systémiques" at his University.

3437

SYSTEMICS (Practical) ²⁾

D. DURAND emits the following "guidelines for a correct use of the systemic **method**" (1979, p.69);

- "5 "negative" guidelines
- not to reduce **variety** in order to simplify
- not to eliminate **uncertainty** or **randomness**
- not to ignore **constraints**
- not to cut **feedback loops**
- not to try to be exhaustive
- "5 heuristic type guidelines
- Favour a revealing **model** over an explanation
- Start with a **synchronic** approach, and follow with a **diachronic** one
- Think of **function** and **structure** alternatively
- Put emphasis on the systems **links**
- Put emphasis on the **regulation subsystem**
- "5 guidelines for **action**
- Define **goals**, better than establish a **program**
- Allow for **autonomy** at each **level**
- Use **information**, more than **energy**
- Take in account **delays** in **responses**
- Maintain **adaptation** margins".

While possibly somewhat too **systematic**, these guidelines are surely useful, and even basic for the **understanding** and the **management of complex situations**.

"**Information**" should include the complete "tool-box" of systemic concepts and **models**.

Systemics should, in the opinion of this compiler, never be considered in a prescriptive way. It could not justify any **ideology**. Such a deformation would become very confusing and dangerous.

3438

SYSTEMICS vs SYSTEMATICS? ^{1) - 2) - 3)}

Systematics is mostly an **arbitrary** mode of **classification**. One example would be arranging a collection of books according to the color of their cover.

However, some **classifications**, at first sight arbitrary, may finally reveal an underlying **general order**.

This was the case for example with MENDELÉEV's table of elements, whose regularities are consequences of the atomic **structures**, that were unknown at the time.

There may thus be a progressive shift from systematics to systemics as the apparently arbitrary **order** is found out to conceal an **algorithm**, which in turn reflects a general **mode of organization**, i.e. significant **correlations** or **interrelations** among the classified items. Such **relations** then become the groundwork for the study of **organized complexity**, i.e. **systemics**.

Systematics can thus be used as a **heuristic** tool in systemics. However, a previous general **understanding** of the systemic **paradigm** is necessary, in order to understand what to search for.

It is to be noted that a purely systematic view impairs many times the **perception** of systemic **order** and even leads to spurious orderings of **data**. Serious cases have been observed in economics and in experimental psychology, for example.

3439

SYSTEM-INQUIRING METHODS (a taxonomy of)^{1) - 2) - 3)}

For G. KLIR systems inquiry covers: "the full scope of activities by which we attempt to construct systems that are adequate **models** of some aspect of reality... (in order) to make adequate **predictions** or retrodictions, to learn how to **control** the **phenomena** in any desirable way, and to use all these capabilities for various ends" (1993, p.30).

KLIR tried to establish a "**taxonomy of systems**" that may possibly be better understood as a taxonomy of **methods** to establish **models** of systems (1988).

He defined the following ideas: we start with an "**experimental frame**", which determines what precisely we are going to register, defining the limits of our inquiring. The basic element in this experimental frame is a "**mask**", i.e., a partialized screen through which we select and observe **states** and **processes**.

Using this basic inquiring device, we define a "**source system**" as a producer of empirical **data**.

Our **observations** usually lead us to the discovery of some "**type of activity**", characteristic of the **source system**. Such **activity data** can be referred to two different aspects of the system:

- The "**behavioral system**", corresponding to time-invariant relations.
- The "**state-transition system**", characterized by a **set** of overall **states**.

Integrating both aspects we obtain the "**structure system**", corresponding to a **set** of interconnected **diachronic transformations**.

→ "**Reconstructability analysis**".

3440

SYSTEM MASK

→ **Mask**

3441

SYSTEM-LEVEL EFFECTS²⁾⁴⁾⁵⁾

One of the most startling system-level effect is that an established system's dynamics may block invasions by new species, even those endowed with superior characteristics.

In Roger LEWIN's words: "The **network of connections** between the species of the mature **ecosystem** protects those species from outside **competition**" (1997, p. 31)

This remains true until the existing **ecosystem** is deeply perturbed, with a considerable disorganization of the **interrelations network**. In such a **situation**, a sudden **collapse** becomes possible.

According to LEWIN, such effects can also be observed in economy: New firms, even with a superior product, could be unable to introduce themselves in the productive circle, due to a kind of global inertia of the existing system.

The disorganization of an **ecosystem** (biological or otherwise) is frequently a progressive **process** and the **collapse** occurs only at a **critical stability threshold**. Some oceanic **ecosystems** have been thus affected in the recent years and one may wonder if similar effects cannot appear in economic and socio-political systems.

3442

SYSTEMOGENESIS¹⁾²⁾

The progressive construction of successive **emergent levels** of **complexity** produced by antagonically interacting **fields**.

When the same **interactions** become repetitive, more or less permanent **processes** appear, which in turn may lead to materialization of more or less permanent **structures**, i.e. **forms**. The concept has been introduced by S. LUPASCO and is based on his **Antagonism Principle**, which in turn results of the combination of **energy dynamics** (as stated in the 2nd Principle of thermodynamics) and PAULI's **Exclusion** principle, which leads in fact to individualization of **elements** (see bibliography)

In different, but equivalent ways, the subject has been tackled by d'A.W. THOMPSON (1916), Ch. LAVILLE (1950), D. McNEIL (1993b), and V. CSANYI (1982, 1989)

→ **Autogenetic systems precursors; Zero system**

3443

SYSTEMOGRAPHY²⁾

"The creation of **models**, **isomorphic** to the "**Système Général**" (J.L. LE MOIGNE, 1977, p.54).

This neologism was introduced by LE MOIGNE to refer to the uses of his "**Système Général**" model.

According to him we should try to "escape from the **semantic contradiction**" in the current expression "**Systems Analysis**" (1977, p. 43).

LE MOIGNE clearly perceives that the **concrete systems** or **objects** are never **isomorphic** with their **models** (nor with each other), but only **homomorphic**, up to a point.

Only the **models** can be **isomorphic**, as the modelizer do construct them according to his intentions, a fact which LE MOIGNE acknowledges as follows: "... every **object**, every aspect of any **object**, in our opinion, is not evident, but merely pertinent in relation to the intention that we lend to it" (p. 55).

He also quotes G. PASK: "Any **pattern of activities** within a **net**, if coherent by some **observer**, is a system" (1960, p. 233).

3444

SYSTEMOLOGY^{1) - 2) - 3)}

A reformulation of so-called **system sciences**, proposed by D. Mc NEIL.

The term was initially proposed by R.L. ACKOFF in 1973: "As the problem complexes with which we concern ourselves increase in **complexity**, the need for bringing the **interdisciplines** together increases. What we need may be called **metadisciplines**, and what they are needed for may be called **systemology**" (1991, p.33).

The basic tenet of Mc NEIL's proposal is that all systems are basically **toroids**, i.e. complex structured **torus**. This is consistent with C. LAVILLE's general concept of **energy vortexes** (1950).

According to Mc NEIL "... no system – properly so-called – can be represented by any less a figure than a three dimensional, **homeokinetic torus** within a **flux of throughput**... At a given **echelon of order**, a system is a **dynamic, organized, delimited, open, persistent, composite whole**. It is **voluntary**, comprising at least one **loop** and at least one **link** which manifest the aspects of **content, form, function** and **control**, together with **timing** and **scaling** factors, relative to an **environment** and relevant to a percipient" ("Percipient" can be viewed as a synonym for "observer", with possibly a shade of GIBSON's way to understand **perception**).

He adds: "The **paradigm**, illustrated as above, offers an organized, constitutive core of systemological **concepts** accessible "by inspection". Having placed the visualization of a systemological **paradigm** into a **toroidal context**, one can proceed to explicate related concepts such as **boundaries, interfaces, stability, succession, trajectories, chirality, polarity, potential, reciprocity, complementarity**, etc... At the same time, a **frame of reference** is established for systemic principles such as conservation, **equipotency, requisite variety, parsimony**, and mutuality... Throughout all of this, the percipient remains pivotal because there is no system – properly construed – except as it is **defined** relevant to **purposes**. By attending to the **toroidal whole**, this systemological **paradigm** accommodates the "real"

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

world which is assured to exist regardless of what any percipient may think as well as the "imaginary" world out of which come the thoughts which define and alter reality".

And "Clearly, a systemological **paradigm** turns many a conventional **worldview** inside-out. To adopt and assimilate it is to re-cognize the world from the **linear**, the **convex**, the **closed**, the **cropped**, and the **particulate**... into the **cyclical**, the **hyperbolic**, the **open**, **continuous** and **vorticate**" (1993).

Mc NEIL's basic paper is profusely illustrated, which makes the understanding of all these statements very clear and easy.

3445

SYSTEMOLOGY (Interpretive)

→ Interpretive systemology

3446

SYSTEMS AGE ¹⁾ - 4)

According to R.L. ACKOFF, (as quoted by M.C. JACKSON, 1992, p.145): "About the time of World War II, the "machine age" - associated with the industrial revolution - began to give way to the "systems age". The systems age is characterized by increasingly rapid **change**, **interdependence**, and **complex purposeful systems**. It demands that much greater emphasis be put on **learning** and **adaptation** if any kind of **stability** is to be achieved. This, in turn, requires a radical reorientation of worldview. Machine-age thinking - based upon **analysis**, **reductionism**, a search for **cause-effects relations** and **determinism** - must be complemented by systems-age thinking, which proceeds by **synthesis** and **expansionism**, tries to grasp producer-product **relations** and admits the possibility of free will and **choice**".

Nowadays, many more characteristics of systems age are emerging as for example general and special **networks development**, a clearer view of **time dimension** in natural and **human systems**, the discovery of the critical relation of **human systems** with their specific **environments**, a better **understanding** at the same time of the **constraints** related to **auto-poiesis** and of the concomitant acquisition of individual and **group autonomy**, etc...

3447

SYSTEMS ANALYSIS ¹⁾ - 2) - 3)

1. "The procedure of studying systems by identifying their **limits** and **parts** (**subsystems**), their aims, programs and effectiveness (O.R. YOUNG, 1974, p.299)

2. "Study and analysis of complex problems in terms of the **relations** between the **subsystems** that form its **component parts** with the **objective** of predicting the **behavior** of the **whole** from that of its **parts**" (UNE Glossary, 1983, p.26)

3. "The **diagnosis**, formulation, and solution of problems that arise out of the complex forms of **interaction** in systems of any kind" (Adapted from K. KRIPPENDORFF, 1986, p.74).

4. "An analysis to suggest a course of **action** by systematically examining the **costs**, **effectiveness** and **risks** of alternative politics or **strategies** - and designing additional ones if those examined are found wanting" (E.S. QUADE, 1963, as quoted by M.C. JACKSON, 1992, p.75).

Systems analysis developed out of wartime military operations (1940-45) and was later extended to the study of **complex systems** in general, notably through the RAND Corporation (set up in 1947).

According to M.C. JACKSON: The **methodology** of systems analysis can be seen as consisting of seven major steps, as follows:

- Formulating the **problem**

- Identifying, designing and screening alternative **responses**
- Building and using **models** for predicting the consequences of adopting particular **responses**
- Comparing and ranking alternative **responses**
- Evaluating the analysis
- **Decision** and implementation
- Evaluating the outcome" (p.76)

Systems analysis is basically oriented to technical systems **planning**, generally without participation of most **stakeholders** and scant consideration for the ways they are affected by the **design**.

KRIPPENDORFF states that this **methodology** is applicable "from hardware to corporations" whose aim is "to accomplish one or more specific **objectives**". Furthermore: "Systems analysis provides a **variety** of analytical tools, **design methods** and evaluative techniques to aid in **decision making**..." (Ibid).

I.G. BLOOR writes: "Systems Analysis covers such a computer-related technique which really bases its principles on Organization and Methods" (1987, p.55). This is of course a much reduced and sheer technical view of systems analysis.

According to J.de ROSNAY, in Systems Analysis one defines "the **limits** of the system to be modeled, identifies the most important **elements** and the **interactions modes** between these **elements**, determines the **linkages** that integrate them in an organized **whole**. **Elements** and **linkages** are classified and **hierarchized**. Next, one seeks and identifies the **flow variables**, the **state variables**, the **positive** and **negative feedbacks**, the **delays**, the **sources** and the **sinks**. Every **feedback** is segregated and its influence on the various subjects of the system is assessed." (1990, p.113). Accordingly to this view, systems analysis should be a preparatory stage for **systems dynamics** runs.

Systems Analysis defines the **data** to be used to build a **model** of the system. However, and unfortunately, in many cases, the **data**, when provided, are incomplete, insufficient or poorly assessed. G. KLIR's "**reconstructability analysis**" aims to improve systems analysis as a **method**.

For L. TRONCALE, systems analysis is the "most **reductionist** of **systems approaches**; the collection, treatment and **validation** of concrete **data** on the multiple **components** of a specific real system; ...often leads to **simulation** of the system for the purpose of quantitative prediction; results are **context-dependent**; ...does not focus on **isomorphies**; (it) relies heavily on the use of mathematical formalisms and the use of the computer; ...leads to usually restricted to the detailed study of one particular system (and) so it is less comparative across different cases, even within a conventional discipline, than **systems theory**; when it does involve **multi-disciplinary** comparisons, it focuses on one **problem**, or **design goal**, using one tool, as in the study of acid rain, or global climate" (1985, p.45).

In synthesis, the technical tool may well limit the vision of the **modelizer** and the scope of the enquiry.

Unfortunately systems analysis has produced in the fifties and the sixties "some exaggerated and highly oversold claims ... as a tool for making public policy" (G. KLIR, 1990, p.166). This situation led to strong criticism by I. HOOS (1972), D. BERLINSKI (1976) and R. LILIENTHAL (1978).

Still more unfortunately, Systems Analysis was frequently confounded with the **Systems Approach**, and as a result, the critique of the former one, in not a few cases, was extended in a superficial way to the latter one. One of the main sources of these negative appreciations has been the somewhat hyperbolic and imprudent use of J. FORRESTER's **Systems Dynamics** in the **Club of Rome** studies. For a balanced appreciation of these critiques see G. KLIR (1991, p.166-8).

3448

SYSTEMS ANALYSIS: Its basic categories ¹⁾ - 2) - 3)

Ch. HITCH, quoted by I. BLAUBERG et al. lists the following "universal logical elements of systems analysis", which BLAUBERG et al. consider to be **categories**:

1. A **goal** or **set of goals**
2. Alternative **means** ("systems") that can be used to reach the **goal** and are **sets** of systems **elements** or **strategies**;
3. **Resource** expenditures on the system;
4. A mathematical and logical **model**, i.e. a system of **connections** between the **goals**, alternative **means**, **environment**, and requirements imposed upon **resources**

5. The **criterion** by which the preferred alternatives are selected" (in BLAUBERG et al., 1977, p.265).

Obviously, systems analysis is "ad hoc": **goals, means, models**, etc... are selected by the analyst, in relation to his own **goals, knowledge** ... and prejudices, and also probably those of the user of the system. This is unavoidable, of course, but should preferably not remain unknown from the analyst, nor from his "client", nor shrouded from the view of other possible **stakeholders**.

3449

SYSTEMS ANALYSIS (Weaknesses in) ^{1) - 3)}

Systems Analysis suffers from various weaknesses. Some are methodological, others are conceptual.

As to conceptual aspects R. TOMLINSON and I. KISS state: "One... assumption was that the "hard" part of the problem – which could be expressed in mathematical terms – could usefully be isolated from the human and organizational **elements** which could thus be eliminated from the analysis. Another false assumption was that implementation was an entirely separate **activity** from the analysis itself" (1984, p.IX).

From a methodological viewpoint, complex **situations** and **nonlinear processes** are many times excessively simplified in order to allow for their study within the **framework** of current mathematics. H. LINSTONE writes: "The analyst has been caught between two unpalatable **choices**: solving **linear**, irrelevant problems and struggling unsuccessfully with **nonlinear** relevant ones" (1989, p.309).

Obviously, using correct mathematics to solve a ill-stated problem leads to illusory **forecasts** and to a false security.

3450

SYSTEMS APPROACH ^{1) - 2) - 3) - 4)}

In general

J.van GIGCH enumerates many different aspects of the systems approach, which "can be regarded as:

"A methodology of design

A common conceptual **framework**

A new kind of scientific **method**

A theory of **organizations**

Systems **management**

A method related to **systems engineering, operations research, cost effectiveness**, etc...

Applied **General Systems Theory**" (1978, p.34)

van GIGCH completes his overview establishing a **taxonomy** of sciences and systems, divided into "hard" and "soft" systems in physical, life, behavioral and social sciences (p.39).

Logical aspects

BLAUBERG, SADOVSKY and YUDIN consider that, from the logical viewpoint, "the development of systems research presupposes:

a) The construction of formal logical systems describing the **process** of reasoning as applied to certain aspects of the systems approach or special systems theories (e.g. the logic of **relations, bio-logics**, the logic of reflexive reasoning, etc...)

b) The formulation of the logical apparatus of the **general systems theory**

c) The metamathematical and metalogical analysis of systems formalisms" (1977, p.125).

Methodological aspects

According to the same authors, the methodological aspects of the systems approach "cover the following tasks:

"a) The explication (including the formal explication) of the basic concepts of the systemic approach, such as **system, element, connection, structure, wholeness, part-whole relation**, etc...

"b) The **classification** of systems, including the discussion and comparison of the various approaches to this problem

"c) The identification and analysis of the specific methods of **systems research** – the systemic (integral) **representation** of a system **object**, the investigation of a system together with its **environment**, the **isomorphy** of systems **concepts** and **laws, systems analysis** and **synthesis**, etc...

"d) The **methods** for constructing the theoretical **knowledge** of systems – both in the case of special systems concepts and in formulating a **general systems theory** (1977, p.125).

J. SUTHERLAND, from another viewpoint on **methodology**, proposed what he called the syncretic approach, "... to insure that the systems **models** we use comprehend to the fullest extent possible both qualitative and quantitative **constructs**" (Quoted from J.D. WHITE, 1977, p.68).

As to the basic nature and limits of the systemic approach, J.C. LUGAN writes: "The systemic approach consists in isolating a number of **elements** n, emphasizing certain types of **relations** that would give a degree of **autonomy** to the system in relation to a more extensive set N of **elements**.

"This global character of systemic **modelization** should not be understood as aiming at exhaustivity. To begin with only those properties considered as essential from the modelizer's viewpoint are taken in account. The **model** can be enriched... (but will never be complete). In other words, systemic **modelization** should tend to be an evolutive **process**, conscious of its limits between a kind of exhaustive perfectionism and an excessively reducing **simplification**" (1993, p.24).

Psycho-sociological aspects

E. HERRSCHER writes: "The point can be made that the systems approach comprises both rational and non-rational **elements**. Particularly since **soft systems thinking** took the lead from the hard system approach, many social, political and psychological **issues** became more relevant, weakening the rational part of the rational/non-rational mix or, at least introducing (in the words of C. FRANÇOIS) a psychical and sociological rationality, complementary to the hard systems approach. Few social scientists would object, but some quantitative or **closed-model-oriented** scientists might" (1995).

The systemic psycho-sociological rationality aspects are of different kinds:

1) The systemic inner and relational workings of societies; **autopoiesis, conflict, hierarchies, interactions** with the **environment; networks, processes, side effects, stigmery, subsystems**, etc...

2) The ways these inner social workings translate into attitudes, **situations** and **issues: values, norms, ideologies**, prejudices, power **relations**, etc...

3) The ways the **modelizer** understand (or not) his/her **observer role** and **choices** when **modeling** some social system, and perhaps his/her **relationship** with members of the latter, who required the intervention.

3451

SYSTEMS (Basic classes of) ¹⁾

G. BROEKSTRA compares two different basic classifications of systems.

In his opinion **closed systems**, wherein only the stable **relations** of the **parts** to the **whole** are considered, can be equated with mechanical (Newtonian) systems. In both case, the **control** is **exogenous** (or **algorithmic**).

Open systems are those in which **wholes** are necessarily related to a specific **environment**, and are fairly similar to PRIGOGINE'S **equilibrium systems**, "as dealt with by classical **thermodynamics**".

Finally, EHRlich and RAVEN's **co-evolving systems** are those whose **relation** to their changing **environment** is constantly evolving and can be compared with PRIGOGINE'S **non-equilibrium systems**, submitted to "... the principle of **order through fluctuation** (that) describes the **phenomenon** of spontaneous **structuration**" (1993, p.74).

Many other classifications have been proposed, considered from widely different viewpoints. Here are some:

- K. BOULDING: from simple "**frameworks**" to "transcendental systems" (1956).
- H.A. SIMON: considering specific systems characteristics in systems from physical to symbolic (1965, p.63-76).
- J. LESOURNE: taking in account a less or more developed degree of **organization** and **autonomy** (1976).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

- J.G. MILLER: His taxonomy of **living systems** based on growing **complexity** or **organization** through 8 **levels** (1978).
 - J.D.R.de RAADT: his multi-modal concept as a base for the characterization of systems on multiple **levels** from "numerical" to "pistic" (1989, p.17-25).
 - K. KORNWACHS and W.von LUCADOU: based on the degree of describability of systems (1989, p.125).
 - G. KLIR: his **epistemological systems hierarchy** referred to levels of **description** and related to his **reconstructability analysis** (1991, p.222 and 344).
- hereafter and "Systems types".

3452

SYSTEMS BEHAVIOR (Modifying) ^{1) - 4)}

The behavior of a **complex system** should be modified only according to a global perspective. Introducing any limited local **changes** will merely lead to their uncontrolled propagation to the whole system, sometimes with disastrous results. This is the key explanation of global disasters, as for example the Aral Sea one. The following systemic **norms**, intended to modify **complex systems** behavior, are adapted from P. BÜTTNER, as resumed by J. BRIGGS and F.D. PEAT (1991, p. 177, French translation used):

- In any system there is a very limited number of **trigger** points that can be used to produce significant and lasting modifications of the systems behavior
- In more **complex systems**, **effects** are more distant from **causes** in **time** as well as in **space**
- Even very few **feedbacks** within the system reduce much its **predictability**
- Neither the **trigger** points, nor the ways to operate on them are obvious
- Worsening of the system's behavior after an intervention frequently precedes any improvement.

A good **understanding** of all these points is a sine qua non condition for any hopefully efficient attempt at **management** of **complex systems**.

3453

SYSTEMS CINEMATICS ²⁾

According to J.L.LE MOIGNE and R. THOM, the label "**Systems dynamics**" applied by J. FORRESTER (1973) to his **models** is "very ambiguous".

R. THOM quoted by LE MOIGNE, writes: "... *A priori*, any **model** involves two parts: a **cine-matics** whose aim is to parametrize the **forms** or the **states** of the considered **process**; a **dynamics** whose aim is to describe the **evolution** through **time** among these **forms**" (1972, p.19).

In some sense these comments are concurrent with those of the author of this work, who thinks that FORRESTER's dynamics is rooted into some more or less implicit postulates about the system's nature and the permanence of its **interrelations** with its **environment** (Ch. FRANÇOIS, 1983).

3454

SYSTEMS (Co-operative) ²⁾⁴⁾

M. JACKSON comments on the co-operative system **model** introduced (in business **management**) by C. BARNARD as early as 1938 (2000, p. 108)

Basically, cooperative systems appear when **groups** of individuals share common **goals** and are **simultaneously** submitted to similar **constraints**. They quickly find out that by sharing **resources** and harmonizing **behaviors** it becomes possible to attain their goals more easily and more economically.

"Sharing" and "harmonizing" imply the need and the shaping of differentiated **structures** and **functions** and, of course, of a general **co-ordinator** and **regulator** of the **subsystems** activities as related to the basic goal of the system (which is **survival** in the most efficient way).

Jackson writes: "Barnard believed his thinking was relevant to all forms and types of **organization**. His aim was to discover features common to executive **functions** in all organizations". Obviously, these basic executive functions are precisely coordination and regulation. But the previous and indispensable condition is a sound **understanding** of the general nature and order of the co-operative systems.

It is useful to note that these functions exist also in a much less specific way in animal and specially insects societies and are now also emerging in **robots** endowed with reciprocal capacities of **communication**.

3455

SYSTEMS (Design)

→ **DESIGN (Systems)**

3456

SYSTEMS DESIGN (Evolutionary)

→ **Evolutionary Systems Design**

3457

SYSTEMS (Domain of): "The field over which they extent" ¹⁾

J.van GIGCH, who gives this definition classifies as follows the domain of systems:

1. Systems are **living** or **nonliving**
2. Systems are **abstract** or **concrete**

3. Systems are **open** or **closed**

4. Systems exhibit a high or low **order** of **entropy** or **disorder**

5. Systems display organized **simplicity**, **unorganized complexity** or **organized complexity**

6. Systems can be ascribed a **purpose**

7. **Feedback** exists

8. Systems are ordered in **hierarchies**

9. Systems are organized" (1978, p.40)

Item 3 is somewhat ambiguous (see corresponding entries, and "**isolated system**"). Points 5 and 9 could be coordinated.

Since 1978, the systems field has enlarged. We should now add to van GIGCH's list:

10. Systems can be **deterministic**, **markovian** or **chaotic**, i.e. more or less **stable** or **unstable**

11. Systems are natural or artificial (**artefacts**)

12. Systems either adapt, or evolve

13. Systems are **allopoietic** (**artefacts**) or **autopoietic** (**organizationally closed**)

As systemics is still in the making, there may still be more to it!

3458

SYSTEMS DYNAMICS: a CRITIQUE ²⁾

FORRESTER himself made one of the most lapidary critical evaluation of his **method**: "A **computer simulation model** is a theory of the **behavior** it creates" (Quoted by K.B.DE GREENE)

He could have added that it is based on the specific **representation** of the **behavior** of the **concrete system** by the **observer-modelizer**.

Among the difficult and yet unresolved problems for the construction of S.D. models, we can list:

- the possibility of misunderstandings between the "owner of the problem" and the modelizer about the nature of the problem at hand;
- the sometimes doubtful value of the **data** that can be effectively gathered from the concrete **situation**;
- the sometimes dubious **criteria** leading to the introduction or rejection of some **elements** within the **structure** of the **model**;
- the possible neglect of some significant **interactions** between the **elements**, or on the contrary the introduction of spurious ones;
- the impossibility to modelize **simultaneity** of **events** taking place at the same moment in different places in the modeled **concrete system**;
- the necessity to reduce the whole **structure** of the **model** to **binary logics**, adapted to the sequentiality of computers;
- the difficulty to retranslate the obtained results in terms adapted to practical intervention on the **concrete system**.

R.L. FLOOD and M.C. JACKSON made an extended critical survey of S.D. (1991, p.78-83), from four different viewpoints:

"Theory

"a)... Putting in place the **feedback loops** which constitute **system structure** and explain **system behavior** is held to be more important than exact **representation** achieved through precise **reductionist methods**. Obviously this leave S.D. open to charges that it lacks scientific rigour and is imprecise... Of course, from the S.D. point of view, adhering strictly to the scientific **method** would exclude it from addressing most of the problem types for which it was originally intended...

"b) **Soft systems** thinkers question the underlying assumption of S.D. that there is an external world made up of systems the **structure** of which can be grasped using **models** built upon **feedback processes**. To **soft systems** thinkers **social systems** are much more complex than this. They are the creative construction of human beings whose intentions, motivations and actions play a significant part in shaping "system" **behavior**...

"c) It follows that the attempt of S.D. thinkers to model external reality is misguided. **Social systems** are not only too complex for this but the subjective intentions of human beings cannot be captured in such "**objective**" **models**...

"d) Since it is held that social reality is too complex to model, **soft systems** thinkers argue that S.D. **models** must be distorted, one-sided reflections of reality. They are **models** from one, often unstated, point of view. In each **model** there is embedded a taken-for-granted **purpose** which can often be associated with the **transformation** that is being undertaken but ultimately relates back to the particular prejudices of the **modellers**.

Methodology

"a) The **hard systems** critique of SD **methodology** is ... aimed at the **modelling process**... In its concern to be of practical use S.D. is not content to wait upon all the necessary **data** becoming available. It seeks to build its systems **models** based upon judgements about **interdependencies** even when **data** are uncertain or missing...

"b) **Soft systems** thinkers similarly derive their critique of S.D. **methodology** from what they see as the theoretical shortcomings of the approach... **Social systems** are held not to be amenable to quantitative investigation. S.D. attempts to use mathematics in a loose fashion on **variables (rates)** and **states (levels)** that are often far from being clearly identifiable.

Ideology

"a) Rather worrying from the ideological point of view is the manner in which SD analysts act somewhat like elite technicians. They see themselves serving **decision makers**, and managers, as experts providing objective and neutral guidance. There is no involvement of other "**stakeholders**"...

"b) S.D. **modellers** using **feedforward control** appear to believe that there are optimal future **states** that we should steer systems towards. However, these **states** are not made explicit. This is particularly worrying in the case of **social systems** which will contain different **groups** espousing alternative aims and intentions. S.D. **modellers** are likely implicitly to privilege the aims of some **groups** over others"...

Utility

"a) **Hard systems** thinkers believe that S.D. **models** are sometimes based upon poor **data**, sometimes ignore extant theories and often do not undergo a rigorous enough **validation** regime...

"b) **Soft systems** thinkers could forgive S.D. its lack of precision in areas where precision is difficult to obtain – scientific exactitude must sometimes be sacrificed for ready practical usefulness. What they cannot forgive is its attempt to present itself as an objective and neutral approach in the **domain** of **social systems** where "**objectivity**" (at last in the usual sense of that word) and "**neutrality**" are impossible to obtain...

"c) A final point of **soft systems** criticism against S.D. concerns the **relationship** S.D. presupposes as existing between analysts and **decision makers**. The S.D. approach sees these **functions** as separate, the analyst simply presenting expert recommendations to the **decision maker**... According to **soft systems** thinkers... the analyst needs to be much more closely involved with the **decision maker**"

D. MEADOWS et al., recognize that the problem of representing possible abrupt **changes** in a Systems Dynamics **model** is still unsolved: "No existing **global model** has been able to simulate these **changes** successfully, and the **models** that generate **changes** in the **structure** of the **model** do it in a mechanistic way. BARILOCHE **model**, with the **transition** from its "projective" to its "normative" face, is a good example of this" (1982, p.165)

This is of course because **data** used are only quantitative and the **models** themselves practically exclude qualitative **change**, notwithstanding the existence of **feedbacks**, meant to be corrective in order to maintain the system **steady**.

The BARILOCHE model, elaborated in Argentina, had pre-defined **goals**, i.e. was qualitative a priori, once and for all, but altogether **deterministic** and prescriptive.

The abrupt **changes** problem is obviously insoluble in **linear** terms, because **complex systems** are normally **chaotic**. It may remain definitively so, as **chaotic systems forecast** is necessarily probabilistic. The only satisfactory **model** of the system would then be the system itself.

3459

SYSTEMS DYNAMICS (Integrated) ²⁾

This interpretation of Systems Dynamics by E. LASZLO (after P. WEISS) is quite different from J. FORRESTER's **models**.

LASZLO writes: "In fact, the organic **functions** commonly referred to as "**controls**", "**regulations**", "**compensations**", and the like, come under suspicion of being instances of organic systems dynamics rather than **mechanisms** with predesigned and ready pathway **channels**. Under such dynamics the appropriate **response channels** form an *ad hoc* as manifestations of an integrated **response** under some such overall **rule** as "most economical maintenance of an ordered **equilibrium state**" or "attainment of a state of minimum free **energy**" (1974, p.118).

These views seem to relate more to the "why" of systems dynamics than to the "how" and could become a better guide to the construction of **models**, because they correspond to the *basic* nature of well connected systems.

On the other hand, this does not resolve the **modelization** problems of **chaos** in **complex systems**. In fact, most systems dynamics models basically postulate **near-equilibrium stability**, aim at maintaining it and do not have much to say when it is lost.

However, in a recent assessment of S.D., K.DE GREENE writes: "There are a number of important realworld **behaviors** of **complex living systems** that classical systems dynamics cannot completely explain. Systems dynamics should be integrated with **dissipative-structure** theory, **synergetics**, **catastrophe** theory, **field** theory and **chaos** theory in order better to explain and to predict **evolution**, the different kinds of **stability** and **instability**, structural **change** and structural constancy, the different kinds of **equilibrium situations**, **bifurcations**, the **emergence** of collective **behavior** and the qualitative **meaning** of **information**" (1994, p.3).

Consequently, DE GREENE states the following "questions of concern": "Does system dynamics theory as it now stands provide the necessary **fit** to the problems of a world that has become increasingly **turbulent** and unstable since the pioneering foundations were first laid? Can system dynamics be enriched with **constructs** from other systems theories? Can a larger **metatheory**, incorporating systems dynamics, be developed?" (p.5).

FORRESTER himself, in "Urban dynamics" (1969), proposed a number of auxiliary **constructs** that could lead to integrated system dynamics. They have been resumed as follows by DE GREENE (p. 5):

"**Complex systems** have many **levels** and multiple, **nonlinear feedback loops**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"System **behavior** is counterintuitive, that is, counter to intuition based on experience with simple **feedback** systems; **cause** and **effect** are not closely related in **time** and **space**."

"**Complex systems** are insensitive to **changes** of many **parameters** or constants."

"**Complex systems** resist most policy **changes** (**changes** in how **information** is used to determine **action**) because the system makes compensatory shifts."

"**Complex systems** can be controlled through influence points because the system is sensitive to a few **parameters** and to some **changes** in **structure**; a policy **change** may lead to the radiation of pressures throughout the system."

"**Complex systems** counteract externally imposed corrective **programs** or applied forces; corrective **programs** displace natural internal **processes**."

"**Changes** in a **complex system** can cause **short-term responses** opposite to **long-term responses**; **conflict** between the two can produce a worse-than-before condition; the **short-term** can lead to **long-term** degeneration."

"**Complex (social) systems** tend to **drift** to a condition of low **performance**, because people adjust their **norms** in such a way that degraded **performance** is perceived as improvement so that they then apply more of the original "corrective" **actions**."

A good case-example is the generally applied policy to "improve" urban and suburban motor car traffic: more cars "need" more roads, while more roads are an incentive for more cars, in a repetitive **positive feedback** which would unavoidably lead to global traffic jam in cities if some negative feedback (natural or planned) is not to introduce some **limit**."

DE GREENE concludes that a "larger systemic effort" is needed to incorporate in Systems Dynamics:

"1. The **stochastic-deterministic, continuous/discrete/ discontinuous evolution** of real world systems."

"2. The family of **equilibrium situations** including **nonequilibrium** and **far-from-equilibrium** as well as **equilibrium** per se and restorable, **perturbation-driven disequilibrium**."

"3. The nature of **critical thresholds** and **bifurcation** points."

"4. The **emergence** of **structural instability** and true, qualitatively different **structural change**, as opposed to functional **change** mediated by **change** in the dominance of **feedback loops**."

"5. The qualitative nature of **information** and the evolution toward gain and loss of collective **information**."

"6. The overall properties and **behavior** of **fields** including **order parameters**" (Ibid).

This program would take in account (as a minimum) THOM's **catastrophes**, LIAPOUNOV's condition of **stability**, PRIGOGINE's **thermodynamics of far-from-equilibrium systems** and **dissipative structuration**, LORENZ, SMALE et al. **chaos**, and HAKEN's **synergetics**. This is evidently quite a tall order.

3460

SYSTEMS DYNAMICS MODEL (Setting up a)²⁾

The following list, established by S. MARTINEZ, shows the main stages in the making of a SD model:

- "1. **Description** of the system. Identification of **elements** and **relationships**."
2. Causal diagram.

3. Precise definition of each magnitude. **Code** of **variables**."

4. FORRESTER diagram or DYNAMO diagram."

5. Equations system."

6. Calibration."

7. **Sensitivity** analysis"

8. Contrasted evaluation of the **model** and use of the **model**: Simulated images and setting." (1993, p.389)

For a detailed description of these stages, see FORRESTER's works. MARTINEZ gives a good summary. R.L. FLOOD and M.C. JACKSON comment extensively on the philosophy, the principles and the **methodology** of S.D. (1991, p.61-86) (See above)

see figure below

3461

SYSTEMS DYNAMICS (Short history of)¹⁾

S. MARTINEZ offers the following synthetic sketch of Systems dynamics history: "In the 1950s, J.W. FORRESTER, a systems engineer at MIT..., was commissioned by the U.S. company **Sprague Electric** to study the extreme **oscillations** of their sales and establish a means to correct them. From previous experience, FORRESTER knew that the essence of the problem stemmed from the **oscillations** present in systems that contain inertia **effects** or **delays** and reverse **effects**, or **feedback loops** as basic structural characteristics."

"In 1961, FORRESTER published his report on *Industrial Dynamics* (M.I.T. Press) which marked the beginning of "S.D. technique", based on the study and **simulation** of the **behavior** of **social systems**. In 1968, *World Dynamics* (Wright-Allen Press) was published, which served as the basis for the MEADOWS and MEADOWS Report to the **Rome Club**, a research project that was published under the title *The Limits of Growth* (Potomac Associates, 1972). It could be said that this report and the extensive controversy it provoked, were actually what popularized Systems Dynamics all over the world."

"At present, Systems Dynamics (S.D.) or **Simulation Dynamics** – as it is sometimes called – is a widespread technique in general use for the **modeling** and study of the **behavior** of any type of system that contains **delay** or **feedback** characteristics" (1993, p.384).

It should be added that the cultural background, as well as some methodological assumptions and even the real **goals** of the S.D. based **World models** have been heavily criticized from various sides, specially in South America. (The Argentine FUNDACION BARILOCHE report).

3462

SYSTEMS ENGINEERING²⁾

An interdisciplinary concerned with the **interactions** of equipment in larger and larger **complex systems**. (adapted from R.L. ACKOFF, 1972, p.4).

L.von BERTALANFFY gives the following definition, more explicit: "Scientific **planning, design, evaluation** and construction of **man-machine systems**" (1962, p.3).

A more precise definition is given by JENKINS: "The science of designing **complex systems** in their totality to ensure that the **component subsystems** making up the system are designed, fitted together, checked and operated in the most efficient way" (as quoted by M.C. JACKSON, 1992, p.74).

ACKOFF states: "In equipment incorporating automatic **controls**, the **systems approach** is almost inescapable." and "The engineer of course, can no more ignore the human **operator** than the personal psychologist can ignore the machine to be operated".

J. WARFIELD, quoting A.D. HALL III, describes as follows the "Seven phases of Systems Engineering" (in time):

1. **Program planning**... in which those **programs** to be pursued are defined and selected
2. **Project planning**... in which the specific projects to be carried out under a **program** are identified and budgeted
3. **System development**... in which the projects necessary to develop the system are carried out and production plans are made
4. **Production**... in which the systems **elements** and the total system are produced, and plans are completed for its **operation**
5. **Installation**... in which the system is installed and programs are carried out for its **operation**
6. **Operation**... in which the system is in **operation** serving its intended use, and plans are made for its eventual replacement or retirement
7. **Retirement**... in which the system is withdrawn from use, to be replaced by a new system, or is modified significantly" (WARFIELD, 1989, p.169).

The same author also distinguishes "Seven steps of Systems Engineering" in the "Logic dimension":

1. Problem definition
2. **Value system design**
3. Systems **synthesis**
4. **Systems analysis**
5. **Optimization** of each alternative
6. **Decision making**
7. **Planning** for action to implement the next phase" (p.171)

All these phases and steps are fully described in quoted reference.

It would seem, from recent man-made disasters (Chernobyl, the Aral Sea, etc...) that ACKOFF's "**complex system**" should be taken in a still larger sense, incorporating planners, finan-

cists, ecologists and many more so-called **stakeholders** (according to each specific **situation**) into global **participative design**, which would obviously be quite slower, but also more secure...

In effect Systems Engineering is still frequently concerned only or mainly with the **machine part** of the **man-machine system**. Also and particularly both points 7s, about "Retirement or replacement" and "Planning for implementing the next phase" are in most cases forgotten... or even brushed under the carpet.

See: "**Interdisciplinarity**"; "**Multidisciplinarity**" and "**Transdisciplinarity**"

As a result, W. GASPARDI et al. state: "Initially it was expected that systems engineering treated as normative **methodology** of **design** of **complex objects** would become a **paradigm** of the rational **theory of design**. However, those expectations have not been fulfilled. Although systems engineering helped modernize the practical designing **process**, yet it contributed very little to the new **knowledge of design**. Its explanatory capacity proved insufficient to form the **design paradigm**" (1995, p.17).

The crux of the matter seems to be that systems engineering - at least when applied to the **design of man-machine systems**, its main general use - does not include sufficiently the psychological and social factors in these **human activity systems**, described by P. CHECKLAND (1972, p.72).

3463

SYSTEMS FIELDS TAXONOMY¹⁾

The following taxonomy has been established by R. RODRIGUEZ DELGADO (1992, p.1156), founder and leader of the systems movement in Spain. Some slight modifications and additions have been introduced (marked +).

GENERAL APPROACHES

Theory of knowledge
Cognitive approaches

Systems philosophy

Systems **ontology**

Systems **epistemology**: (**holism** vs. **reductionism**)⁺

Systems **ethics**⁺

General semantics⁺

Axiology

Aesthetics

General Systems Theory

Transdisciplinary approach

Generalization of main scientific principles

In monodisciplinary sciences⁺

In **interdisciplinary** sciences⁺

THEORIES OF GENERAL SYSTEMICS USE²⁾

(all added)

Communication and **information** theories

Cybernetics (1st, 2nd and of 2nd order)

Taxonomy of living systems

Thermodynamics of near and far-from-equilibrium systems

Theory of **catastrophes**

Theory of **deterministic chaos**

Theory of **fractals**

Theory of **games**

Theory of **networks** and **automata**

Theories of **autopoiesis** and **autonomy**

Theories of **artificial intelligence** and **life**

Theory of **hierarchical levels**

Topology⁺

Systems methodologies

General **methods** (metaphors, analogies, linkages, isomorphisms⁺)

Co-participative design⁺

Formal and special **languages**⁺

Operational research

Reconstructability analysis⁺

Systems management

SYSTEMIC INSTRUMENTS

Simulation models

Electronics

Graphics

Informatics (i.e. computer science), etc...

3464

SYSTEMS FIELDS THEORY^{1) - 2) - 4)}

System fields theory is proposed by K.DE GREENE for the study of world society within its natural **environment**. He enounces however very general **laws** that makes it a real **systemic** theory, somehow reminiscent of d'ARCY W. THOMPSON's and LAVILLE's ideas about fields.

The **laws** enounced by DE GREENE are as follows:

"First, system fields display different **equilibrium-related behaviors**. Simplest is **equilibrium** and **disequilibrium**, a displacement from **equilibrium** that can be restored by **neg-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

active feedback processes... A more complex example is **homeostasis**. Cybernetic theory and **design** can apply to such systems that can exist or function but cannot change **structurally**. Under **far-from-equilibrium** or **non-equilibrium** conditions, **stability** may break down as powerful driving forces attempt to restore the system to **equilibrium**.

"A **second law** is this: Under **nonequilibrium** conditions the system may be especially susceptible to **fluctuations** that under 'normal' conditions would have been **damped**, and to external **fluctuations**. For **far-from-equilibrium** situations, reconfigurational-systems theory replaces cybernetic theory...

"A **third law** states that systems evolving or driven **far- from- equilibrium** may increasingly approach **critical points** or **thresholds**, or **bifurcation** points, beyond which lies **structural change** (e.g., a **phase transition**). Near the **critical point**, the susceptibility to **fluctuations** increases immensely.

"A **fourth law** states that, as a system-field evolves, the **elements** become increasingly **correlated**, eventually encompassing the entire field. In system-fields that are both highly **correlated** and in the **vicinity** of a **critical point**, just one more incremental **change** may engulf the entire field" (1991, p.64).

In such case, as implied by this author, **forecasting** becomes very difficult.

"A **fifth law** states that an evolving system-field may be described as an **order parameter**. An **order parameter** characterizes **micro-macro interrelationships**. **Interactions** at the more **micro-level** generate a field at a more **macro-level**, the **order parameter**, that reciprocally regulates **behavior** at the **micro-level**" (Ibid).

This corresponds obviously to HAKEN's **slaving principle**, in **synergetics**.

"A **sixth law** states that, because of the existence of **attractors** in **phase space**, the future **state** of the system may be unknown, or even unknowable, and that the future **evolution** and **behavior** of the system may be partly or wholly unpredictable" (Ibid).

DE GREENE adds: "From these loosely stated **laws**, various principles, valuable in the **description** and **prediction** of the **evolution** of system fields, can be deduced...

"When the system evolves or is driven **far-from-equilibrium**, then:

"**Principle One**. The system may be hypersensitive to small **fluctuations** that under 'normal' conditions would have been **damped**, and the frequency of related **fluctuations** may increase.

"**Principle Two**. The system may be hypersensitive to external **perturbations** and **fluctuations** (**noise**). And because of critical slowing down, the system may take longer and longer to recover from **perturbations** and **fluctuations**.

"**Principle Three**. **Microlevel changes** may be indicative of incipient **structural change** even though the system appears 'normal' at the **macroscopic level**" (Ibid, p. 64-65).

These **laws** and principles have evidently a great practical value.

3465

SYSTEMS HEURISTICS (Critical)^{1) - 2) - 3)}

W. ULRICH advocates a "Critical systems heuristics" in order to maintain a continuous reflection on the inevitably partial character of our **understanding** and **design** of **complex human systems**.

ULRICH enounces "Twelve Critically-Heuristic **Categories** of **Pragmatic Mapping**" to be used to obtain a good **representation** of **human systems**, including motivation, **control**, expertise, and legitimation from the different viewpoints of those affected and those involved. (1983, p.244-64).

3466

SYSTEMS IDENTIFICATION^{1) - 3)}

L. A. ZADEH observed that: "the problem of systems identification is one of the most basic, and paradoxically, least-studied problems in **system theory**" (1991, p.320).

The most complete formal **methodology** for systems identification (and precise description) is G. KLIR's **Reconstructability Analysis**.

In practice, systems are empirically identified by **observers** who state, mostly without much ado: "This is the system" This frequently leads to **underconceptualization** (WARFIELD) and a possibly very incomplete **description** of the **concrete system** considered, leading in turn to unsatisfactory **modeling**. J. WARFIELD's **Interpretive Structural Modeling methodology** is another valuable tool to avoid this kind of problems.

3467

SYSTEMS INQUIRY^{1) - 3) - 4)}

"The full scope of activities by which we attempt to **construct** systems that are adequate **models** of some aspect of reality" (G. KLIR, 1991, p.77).

KLIR comments: "The **purpose** of systems inquiry is to understand some **phenomenon** of reality, to make adequate **predictions** or retrodictions, to learn how to **control** the **phenomenon** in any desirable way, and to utilize all these capabilities for various ends..."

"We can say that in both systems inquiry and **systems design**, we **construct** systems that are adequate **models** of" something" (Ibid).

There is of course the problem to define what we understand, as **observers**, by "adequate", and as possible actors as "desirable". A long experience demonstrates that opinions and **viewpoints** vary considerably on these aspects (in time as well as in **space**).

For more rigor about the first one, we should expand as much as possible our **knowledge** of the **phenomenon**, **situation** and system, using for instance WARFIELD's **Interpretive Structural Modeling** and/or KLIR's **Reconstructability Analysis**. As to the desirability aspect, we should furthermore "observe the **observers**", in von FOERSTER's terms, or emulate ACKOFF's fables, to better understand our own and others' motivations.

3468

SYSTEMS (Isomorphic)^{2) - 3)}

Two, or more, **systems models** whose features are equivalent.

Only **models** can be isomorphic. No **model** is totally isomorphic to a **concrete system**. Isomorphic **models** occupy a specific **level** in the whole **taxonomy of abstract systems**.

G. KLIR explains this as follows: "The largest and most fundamental **classes** of systems are those associated with the described **epistemological** types. They are further classified by the various **methodological distinctions**. The more of these **distinctions** are introduced, the smaller **classes** of systems are obtained. The smallest **classes** of systems are reached when systems become totally equivalent in terms of their relations, i.e. isomorphic with each others" (1991, p.222).

This is a **top-down** interpretation.

Another, **bottom-up**, seems possible, in step with increasing degrees of **abstraction**, as shown by KORZYBSKI in his **structural differential**: More and more general **categories** of **objects** can be represented through more and more abstract "**labels**", with a diminishing number or more and more general characteristics. In this sense, for instance, **networks** of different types can be isomorphically characterized, being different however from **hierarchies**, another type of isomorphic **models**.

It would seem that both ways lead to the same general systemic result.

For another angle see: "**SYSTEM (Isomorphic)**".

3469

SYSTEMS (Joined, or coupled Dynamic)²⁾

W.R. ASHBY explains thus the concept: "To join two systems, A and B say, so that A affects B, A must affect B's conditions. In other words, the values of some of B's **parameters** (perhaps one only) must become **functions** of (dependent on) the values of A's **variables**" (1960, p.77).

According to ASHBY: "This **concept** is of the highest importance in biology, in which it occurs frequently and prominently. It occurs whenever we think of one system having an effect on another, or **communicating** with it, or forcing it, or signalling to it" (p.76).

He develops the concept as follows: "In very simple cases, the **behaviour** of the **whole** formed by joining **parts** can be traced step by step by logical or mathematical deduction. Each **part** can be thought of as having its own **phase-space**, filled by a **field**; which **field** it is will depend on the position of the other **part**'s representative point. Each representative point now undergoes a **transition**, guided by its own **field**, whose form depends on the position of the other. So step by step, each goes forward guided by the other and also guiding it." (The **process** has been traced in detail in 1969, Sections 4/7).

"This picture is too complicated for any imaginative grasp of how two actual systems will behave; the details must be worked out by some other **method**. What is important is that the nature of the **process** is conceptually quite free from vagueness or **ambiguity**; so it may properly be included in a rigorous theory of **dynamic systems**" (p.77).

3470

SYSTEMS KNOWLEDGE¹⁾ - 3)

The body of concepts, **principles**, **laws**, **methods** and **models** that aim at the better **understanding** of complex **concrete** or **abstract wholes**.

As observed by G. KLIR, there is a progressive accretion of such **elements** going on since 1948 (with the first von NEUMANN, WIENER and SHANNON's research) (1991, p.219).

KLIR states that there are two basic ways to obtain systems knowledge:

- "mathematically derived knowledge", with the progressive emergence of formalisms specifically adapted to the study of **complex systems**" (numerous examples in this encyclopedia).
- "experimentally derived systems knowledge... obtained by performing and analyzing experiments with systems simulated on a computer or, possibly, in some other way".

KLIR believes that: "The computer plays undoubtedly the most important role in this respect and it is perfectly proper to view it as the *systems science laboratory*" (p.219-20). This will probably become still truer with **connection machines** and highly **parallel** ones.

However great care should be taken not to "artificialize" real **situations** were human **observers** and actors may introduce **values**, **norms**, motivations, prejudices, etc... practically impossible to translate in **bits** and **bytes**.

3471

SYSTEMS METHODOLOGIES¹⁾ - 2)

There are various types of systems methodologies, according to their respective aims and uses. (see G. DYER, ISSS, 1992, p.1186). Hereafter a probably quite incomplete listing:

- **Hard Systems Methodology**: "Systems-based methodology, also known as **"systems engineering"**, for tackling real world problems in which an **objective** or an end to be achieved can be taken or given. A system is then engineered to achieve the stated **objective**" (R. RODRIGUEZ ULLOA, Glossary, 1999)

The objective is in general functional, material or organizational in quite precise limits. Human psychological, social and cultural factors are not considered.

- **Soft systems methodology**, applicable to ill-structured problems (P CHECKLAND and his followers, principally in England, including more evolved **Total System Intervention** - M.C. JACKSON, R.L. FLOOD and others)
- **Global Design and Interactive Management**, based on **Interpretive Structural Modeling** and assorted practical **networking methods** (J. WARFIELD and followers in U.S, Mexico and various developing countries)
- **Architecture of Complexity**, applied to the study of the internal **structures** of **complex systems**, in order to manage them rationally (H. SIMON)
- **Reconstructability Analysis and General Systems Problem Solver**, aimed at creating more adequate **models** of **complex systems** and ways to manage them (G. KLIR)
- **Coparticipative Design**, aiming at a better integration of human groups in their own **design** projects (B. BANATHY and the FUSCHL Group)
- **Management Science**, developed principally along **metadisciplinary concepts** and corresponding practical **methods** (R.L. ACKOFF and his Pennsylvania University team)
- **Systems Dynamics**, developed in order to simulate **complex systems** on computers (with sometimes doubtful results) (J. FORRESTER and his M.I.T. team)
- **The Viable System** modeling, aimed at defining the basic **parameters** of **complex systems** in order to modelize them and evaluate their **viability** or the **changes** to be introduced (S. BEER)
- **Expert systems**, based on human experts **knowledge** transferred to computers and applicable to specific **situations**

In some cases **Systems Analysis** and **Systems Engineering** techniques are used within these larger **reference frames**.

3472

SYSTEMS MOVEMENT¹⁾

"A loose association on worldwide scale of people from different disciplines of science, engineering, philosophy, and other areas, who share a common interest in ideas (concepts, principles, **methods**, etc...) that are applicable

to all systems and that, consequently, transcend the **boundaries** of traditional disciplines" (G. KLIR, 1991, p.19).

KLIR offers a synthetic history of the systems movement in this reference (1991, p.19-39 and p.346-7). P.B. CHECKLAND also develop an interesting evaluation in the same collective work (p.259-68).

The systems movement however, after 40 years, find itself in a serious predicament.

The following harsh critical **evaluation** of the systems movement by D. H. Mc NEIL is well worth of attention.

"The modern history of the "systems movement" began with the complicated organizational demands during World War II. In subsequent decades, very large governmental, corporate, aerospace, and computer **operations** engendered systemic developments. One might expect the theoretical foundations of **"systems thinking"** to have progressed apace, but such has not been the case. If anything, there is less **relevance** and less credibility in the systems professions today than at any time since von BERTALANFFY set forth the **goal** of a **"General Systems Theory"**. University curricula in systems are now being dismantled or merged with other subjects. Professional societies concerned with the subject matter of systems are weak and philosophically adrift.

"The "systems movement" has failed and its offshoots in the "environmental movement" will fail also unless some changes are made. After nearly half a century of fitful efforts, there is no comprehensive theory of systems, no standard textbook of fundamentals and no definitive workbook of techniques and applications. Attempts to produce politically correct systems studies within the conventional Science of engineering curricula have only served further to emasculate the contribution that systemological discourse would make on its own merits.

"The "systems movement" has been its own worst enemy. It has utterly failed to define itself and its subject matter and has not established itself as a discipline. On the one hand, this invites charlatans to preempt its concepts and misrepresent them. On the other hand, it prompts its professionals to seek respectability within the purview of conventional sciences...

"There will be a great deal of consolidation and clarification to do" (1992, p.1077-8)

Unfortunately, there is much truth in Mc NEIL'S indictment, even if it will probably forever be difficult - and inappropriate - to transform **systems thinking** or **systems approach** into a "discipline". This would put it nicely in a small and segregated intellectual **niche**, while it really should become the basic ground for *anybody confronted with complex situations of any kind, anywhere at any time, i.e., all of us!* This systems literacy general need is for sure a very difficult problem of educative **design** (F. CROWELL, 1992, p.964-975).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This encyclopedia tries to offer general **information** on systems views and to promote **semantic** clarification. It may possibly also be helpful to convey a clearer view of the "agglutinating" and connective global character of **systemics**, in the hope that this could lead to a better general and ordered formulation of "**systems thinking**".

However, much more fundamental material should be produced, and practical ways to perfect them and transmit them should be invented.

It should also be noted that very interesting and useful synthetic work has been done outside the anglo-saxon world, specially in France (J.L. LE MOIGNE, E. MORIN) and in Germany (G. KLAUS). Good systemists should cultivate a worldly connected perspective!

... And should urgently put it to practical uses.

3473

SYSTEMS PATHOLOGY

→ Pathology of complex systems

3474

SYSTEMS PHILOSOPHY^{1) - 3)}

W. ULRICH (1983, p.321-3) has imagined a hypothetical debate between H.A. SIMON and C.W. CHURCHMAN, two outstanding systemists whose views are at odds on a number of points. ULRICH extracted the **elements** of this fictitious debate from SIMON's "Science of the Artificial" and from CHURCHMAN's "The Artificiality of Science". Hereafter, a short summary of this debate (on which thesis ULRICH obtained both supposed contenders' agreement):

For more precise information see reference.

see table below

Table: see entry **SYSTEMS PHILOSOPHY**

Position	H.A. SIMON	C.W. CHURCHMAN
Subjectivity is	avoided	not avoided
Complexity is	hierarchical	not hierarchical
Wholeness of systems (holism) is	denied except in a pragmatic sense	critically considered
Reducing complexity of systems to "simple" subsystems is	a source of knowledge	a source of irrelevance
The purposeful character of systems (teleology) is	denied (teleological fallacy)	critically considered
The decomposability principle is	accepted	rejected
The description of systems must	focus on redundancy	focus on uniqueness
The crucial design task to be solved is	problem decomposition	problem identification
The designer's main tool is	objectivity	subjectivity

In a more taxonomic way, R. RODRIGUEZ DELGADO describes as follows the different possible meanings of so-called systems philosophy:

"a) A global attempt to understand the Universe and the existence of Man

"b) A partial generalization of **knowledge**, like Philosophy of History, Philosophy of Science, Philosophy of Art, etc.

c) An **Ontology** or Theory of the abstract Being

d) An **Epistemology** or Theory of Science

e) An instrument for reaching a synthesis of scientific **knowledge**

f) A way of orienting human **action** in an intelligent way

g) An instrument for the positive transformation of Man and Society" (1993a, p.20).

This author sees in systems philosophy a trend toward the integration of different or even opposed philosophical systems, as elaborated for example by Nicholas of CUSA, THEILHARD de CHARDIN, J. ORTEGA Y GASSET, Karl MARX and E. LASZLO.

Conversely, R. RODRIGUEZ ULLOA speaks of a "**Weltanschauung**", wherein a philosophy is merely implicit.

3475

SYSTEMS REPRESENTATION²⁾

Any way to construct a **model** of a system.

Really **complex systems** can practically be represented only at the price of gross simplification in some coarse **homomorphic** form, using for example an **aggregation mode**. A good example are the **models** used in **Systems Dynamics**.

This is not to disparage such **models**, which are the best available for practical **purposes**, but only to take a clear view of their limitations.

Only what M. BUNGE calls systems with a "denumerable composition" as "a molecule or an industrial plant" (1979, p.16-7) can be adequately represented by a **graph** or its equivalent **matrix**, or the corresponding set of equations.

BUNGE acknowledges that: "Obviously neither the **graph** nor the **matrix** representation of a system suffices for all **purposes**. It represents only the composition, **structure** and **environment** of a system with neglect of its **dynamics**. A more complete representation can only be obtained by setting up a full fledged dynamical theory incorporating and expanding the **information** contained in the **graph** or the **matrix** representation... namely the **state space representation** (p.19-20).

Even this supposes hypotheses about the system, derived from a more general **frame of reference**.

3476

SYSTEMS RESEARCH^{1) - 2) - 3)}

"The totality of scientific and technological problems (research and development) which, in spite of their variety and specificity, have one substantial feature in common

According to BLAUBERG et al.: "the main tasks of the logic and **methodology** of systems research may be listed as follows:

- the construction of **conceptual means** - systems of concepts, conceptual **models** of a special type, etc... - for the expression (**representation**) of the **systems nature** of corresponding **objects**.
- the evolvement of **apparatus** for the **description** of the most important characteristics of systems **objects** - **connections** (including their typology), systems of **connections**, **interrelations** of system and **environment**, the **hierarchical structure** of systems, problems of **control**, etc..
- the construction of **formalized systems** for the **description** of systems **objects**, including the formulation of specific **rules of inference** for such systems" (Ibid, p.88).

3477

SYSTEMS SCIENCE^{1) - 3)}

"That field of scientific inquiry whose objects of study are systems" (G. KLIR, 1993, p.27).

The word "science" has evoked a serious resistance among "hard" scientists, because of the very general and abstract meaning of "system", the supposed **object of inquiry**.

Still less adequate seems to be the expression "systems ScienceS" (as it appears now in the official name of the "**International Society for the Systems Sciences**"), evoking a more or less unorganized ragbag of scattered disci-

plines, and encouraging systemists to seek "a politically correct shelter for their work under the umbrella of orthodox science" (D. Mc NEIL, 1993b).

This has been sensed by quite a number of "system scientists", as for instance L. TRONCALE, who considers this expression as merely "a collective non-specific term... and a questionable use of the term "science" similar to that found in "social science" (1984, p.45).

KLIR himself adds: "Unfortunately, this definition, which appears reasonable on the surface, only begs the question. To make it operational, and thus useful, we have to establish some broad and generally acceptable characteristics of the concept of a system." (Ibid). The whole of this KLIR's paper on the subject is dedicated to a "guided tour" of this difficult task and can be used as an introduction to the subject.

Some interesting statements by KLIR:

"Classical science, which is predominantly oriented to thinghood properties, and systems science, which is predominantly oriented to systemhood properties, are two distinct perspectives from which scientific inquiry can be approached. These perspectives are complementary. Although classical scientific inquiries are almost never devoid of issues involving systemhood properties, these issues are not of primary interest to classical science and have been handled in an opportunistic, ad hoc fashion.... While the systems perspective was not essential when science dealt with simple systems, its significance increases with growing **complexity** of systems of our current interest" (p.28-29).

On the role of the computer in relation to "systems science", KLIR states: "The computer has, in fact, a dual role in systems science. In one of the roles, it is a methodological tool for dealing with systems problems. In the other role, it serves as a laboratory for experimenting with systems" (p.38).

(This last aspect is now becoming very significant in the field of **artificial life**).

KLIR also states that the study of "systemhood" starts with the development of "... a comprehensive conceptual **framework** by which the whole spectrum of conceivable systems is divided into significant **categories**. The second step is to study the individual **categories** of systems and their **relationships**, and to organize the **categories** in a coherent **whole**. The third step is to study systems problems that emerge from the underlying **set** of organized systems **categories**. Finally, we address methodological issues regarding the various types of systems problems" (p.38).

"**Simplification methods** are crucial for dealing with **phenomena** of organized **complexity**. Since organized **complexity** is the prime territory of systems science, these **methods** play a key role..." (p.47).

F. HEYLIGHEN states: "Systems science (including cybernetics) is not a traditional discipline concerned with the study of a particular **domain**, but a meta-discipline, concerned with the **domain-independent** modelling of general systems. (van GIGCH). As such, it does not aim to find the one true **representation** for a given type of systems (e.g., physical, chemical or biological systems) but to formulate general principles about how different **representations** of different systems can be constructed so as to be effective in **problem solving**" (1990a, p.423).

Should there be *systems scientists*? G. KLIR so believes: "The role of developing and applying the systemhood expertise must be undertaken by a scientist of a different kind, a *systems scientist*, whose specialization is this very expertise" (1991, p.23). This seems at the same time correct and doubtful. It is correct because we undoubtedly need people able to understand, explain and, in many cases, manage **complex systems**. A systemic formation should be a very general feature of **knowledge** acquisition. This explains however why the idea could be questioned: If systems science becomes an academic specialty, it could promptly be relegated in some more or less secluded academic cloister and become lost for the millions who really need it.

Systems science is a meta- or trans-discipline (or, possibly better, a **meta-methodology**) for everybody and should not be simply reduced to a discipline status, even when and where it must be taught. In KLIR's words: "Systems science has also its own **methodologies**, which I view as a coherent collection of **methods** for dealing with those types of systems problems that emanate from a particular conceptual **framework**. Furthermore, systems science has its own **metamethodology**. Its purpose is to determine characteristics of individual **methods** (such as computational **complexity**, **performance**, and range of applicability) and utilize these characteristics for selecting the right **method** for a given problem in a specific **context**."

"In spite of all its science-like characteristics, I argue... that systems science is not a science in the ordinary sense, but rather a *new dimension in science*" (1991, p.352).

This has much to see with the future of Systems Science, another subject widely tackled by KLIR (1991, p.185-90). On one hand, concepts, **principles**, **methods** and **models** – i.e. the scientific aspects – should be constantly extended in order to increase **complexity understanding** for practical and theoretical uses. On the other hand, a general **strategy** and **tactics** should be devised to bring **systems knowledge** to those who could benefit from it – i.e. the sociological and ethical aspects, in terms of the systemists responsibility.

According to G. ANDERSEN: "Systems science can be considered as a human evolutionary system with emergent properties – the **structure** of the **components** changes over time and new **information** is created out of this **process**" (1995, pers. com.).

3478

SYSTEMS SOCIETIES¹⁾

A considerable number of Societies interested in systems have appeared worldwide. However, most of them are merely concerned with some special aspects of systems, as for example: Artificial Intelligence, Computer Science, Fuzzy Logic, Operation Research, Systems Dynamics, Systems Engineering, Systems Simulation, etc...

If Systemics and Cybernetics are to be considered as the hard core of which more specialized disciplines are kinds of conceptual satellites, the following list of Societies seems to cover the field in a quite exhaustive way:

- American Society for Cybernetics
- Argentine Society for Systemics and Cybernetics
- Austrian Society for Cybernetic Studies
- Centre for Systems Studies (University of Hull)
- Collège de Systématique de l' AFCET (Paris)
- European Systems Science Union
- Hellenic Systems Society
- Instituto Andino de Sistemas (Peru)
- International Association of Cybernetics (Belgium) (Dissolved in 1999)
- International Federation for Systems Research (Linz)
- International Society for the Systems Science
- International Systems Institute (Carmel, CA)
- Italian Association for Research on Systems (Milano)
- Polish Systems Society (Wroclaw)
- Slovenian Systems Society (Maribor, Slovenia)
- Spanish Society for General Systems (Valencia, Spain)
- Swiss System Society (Neuchâtel)
- Systeem Groep Nederland (Amsterdam)
- United Kingdom Systems Society (Hull)
- World Organization of Cybernetics and Systems (Paris)

Most of these Societies are active organizations, which organize events, have research groups, and publish books, booklets and in some cases, a Newsletter or a Journal. For details, see, in most cases, specific heading.

There are some other Societies, whose existence seems merely nominal, as well as a number of informal groups in different countries, some of which will probably become officially Systems Societies.

3479

SYSTEMS TEACHING¹⁾

A number of universities have launched programs for systems teaching. Unfortunately, most of them were partial and generally dominated by some more specific systems applications as **systems analysis**, **systems dynamics**, **systems engineering**, or conceived merely as a kind of vague humanistic cultural complement.

In the first case they were frequently considered by specialists as useless, and even a hindrance in technical applications because of their "fuzzy" character. In the second case, they were merely viewed as an ornament without real content. In all cases, they were evaluated as not leading to any specific professional activity (which is of course not the point, even if the "job" is the main concern of nearly all students). As a result, they were generally shunted of downright suppressed.

One of the best recent attempt to introduce a "Master of **Systems science**" degree has been at the **operational research** school of University of Valencia, Spain. (L. FERRER FIGUERAS, 1992, p.1168-74).

One wonders:

- if systems teaching should not be first based on the study of practical **situations** (generally **messes**!) in a great variety of fields;
- if it should not be introduced already at high school and introductory college **level**, not as a specific subject matter, but as a **methodology** perfusing *all* subject matters;
- if the same **methodology** should not be promoted at universities, for example in extra-curricular discussions; and inter-departmental research programs on **complex situations**.

3480

SYSTEMS (Technical Macro-)

→ **Technical Macro-Systems**

3481

SYSTEMS TECHNOLOGY¹⁾

The open **set** of **models** (**functional**, **structural**, **hierarchical**, **catastrophic**, **chaotic**, **dissipative**, **thermodynamical**, etc...) which are available for **systems research**.

This is "quantitative systems science" and "Under the various headings of **systems engineering**, **management science**, **operation research**, computer science, etc., systems **concepts** are translated into operational terms" (E. LASZLO, 1972, p.9)

3482

SYSTEMS: the THERMODYNAMICAL viewpoint¹⁾

From the thermodynamics viewpoint, systems may be differentiated within three basic **categories**, which E. SCHWARZ describes as the follows:

"Non-conservative systems are called dissipative, since part of their energy dissipates as heat" (1990, p.100).

It should be observed that all **concrete systems** are non-conservative. Furthermore the "equilibrated" systems of whom the author speaks in the next paragraph as having attained "the state of maximum **disorder**", are devoid of **structures** and incapable of carrying out any **function**.

SCHWARZ pursues: "The **closed systems**, isolated from the **environment** find themselves either equilibrated (characterized by a maximum **entropy**, i.e. in a **state** of maximum **disorder**), or near the **equilibrium**, in this case they tend towards the **equilibrium state** (maximum **entropy**)" (Ibid).

The so-called "**isolated system**" is a mere **abstraction** (See the discussion of the terms "isolated", "closed", "open") which serves to explain the **2d. Principle of thermodynamics**. An imperfect **model** of such a system can be obtained by enclosing a gas in a tight container. Such a "system" is however unable to develop any organized **activity**.

Next E. SCHWARZ describes "the **dissipative-open systems**... near the **equilibrium**... described by a quite precise equation, which permits to compute the **stationary state** towards which they tend" (Ibid). See "**Systems near equilibrium**".

Finally: "The **dissipative-open systems far away from equilibrium** are described by differential equations where the relation between the general forces and the **flows** is not anymore **linear**" (Ibid. p.101).

These systems may evolve "toward a (more) organized **state**, with decrease of internal **entropy** (by importing **negentropy** from their **environment**)" (Ibid, p.102).

This last statement is debatable at least in its formulation. Highly organized systems have a higher **rate** of **entropy production**, which is the price they have to pay for their superior degree of **organization**. However they maintain this by discharging in their **environment** considerable quantities of degraded **energy**.

3483

SYSTEMS THEORY^{1) - 2) - 3)}

"The generalization of explanations from several analytical studies in order to understand a complex **phenomenon** or **process** within a discipline" (1985., p.45).

L. TRONCALE sustains his definition explaining that systems theory "often leads to a **model** of the **process** with the purpose of achieving a subjective, qualitative **understanding** of the **phenomenon** that goes beyond the quantitative **knowledge** obtained from the specific cases... (and) emphasizes broader comparisons than **systems analysis** across different specific systems within a discipline or **phenomenon**; (it) uses some **isomorphies**, but many fewer than the full **set**; overall, systems theory is one step more abstracted than **systems analysis** in its use of mathematics".

The qualitative aspect in systems theory are indeed dominant, while quite more than subjective. Systems theory also evades of the **limits** of disciplines.

It however does not seem obvious that systems theory uses more mathematics and in a more abstract way than **systems analysis**, nor that this should be its unavoidable **goal** or necessity.

More generally, it seems that systems theory, if such an embracing thing already really exists, is taking shape through a slow interconnection and **interaction** of an array of concepts and **models** coming from very diverse disciplines.

Numerous examples could be given. Here are some:

- **dissipative structuration**: a concept coming from chemistry and **thermodynamics**, but useful in social **ethology** and in social sciences.
- **deterministic chaos**: a concept that originated in celestial mechanics, astronomy and meteorology, but now allows for the interpretation of numerous **phenomena** in multiple disciplines.
- **feedback**: a practically universal **model** of **regulated** or **controlled processes** in any **class** of **complex living** entities and mechanical devices.
- **autopoiesis**: a nearly universal **model** of the way complex entities constantly reconstruct themselves and secure their **autonomy** and **survival**.
- **networks**: a more and more generalized **model** of interactive **behavior** between **elements** leading to global **coherence**.

(For a more complete list see numerous entries in this work).

It should however be strongly emphasized that systems theory is not merely an unorganized collection of more or less systemic theories coming from specialized disciplines. Such theories (as for instance, **control** theory) can usefully contribute to systems theory as a whole, but only if properly integrated in a global **transdisciplinary** perspective, i.e. correctly interconnected with each others.

This is even true of various very promising general theories recognized as typically systemic: HAKEN's **Synergetics**, SABELLI's **Process theory**, MILLER's **Living systems**, Mc NEIL's **Systemology**, LE MOIGNE's *Théorie du Système Général*, for instance.

Possibly, systems theory still lies in the future, if it becomes one day possible to establish a genuine integrating **metatheory in systems research** from the still presently growing **set** of generalising concepts and **models**.

Such a systems theory could instate a new **level** of metascience.

3484

SYSTEMS THEORY ("Hard" or "Soft")^{1) - 3)}

"Hard" Systems Theory

J.van GIGCH describes the nature of so-called "Hard" Systems Theory, as "the continuation of the influence of sciences such as physics and mathematics".

"Hard" Systems Theory and the sciences from which it derives demand rigor and strict quantification. They rely on the deductive **paradigm** and on exact **rules** of procedure and proof... Hard Systems Theory usually provides good descriptive **models** of the **universe** but poor normative ones" (1978, p.73).

"Soft" Systems Theory

According to van GIGCH, "Soft" Systems Theory "views a system as a portion of the world that is perceived as a unit and that is able to maintain its **identity** in spite of **changes** going on in it" (from A. RAPOPORT, in "G.S. Yearbook, Vol 15, 1970, p.15-25).

"Soft systems ... may adopt several **states** due to **environmental** conditions yet preserve their original **identities** in spite of these influences. The solar system, a fountain, a family, a beehive, a city, a nation, and a business firm are systems that undergo continuous **changes** in their **component elements** and probably in their outward perceived shape. Systems defined as soft systems have **structure**, react to the **environment** by changing their **short-term functions**, undergo slow **long-term changes**, but maintain **identity** and evolve" (p.74).

"Soft" Systems Theory faced a strong resistance from many "Hard" Systems scientists, disorientated by what seems to them a lack of methodological rigor.

The well-known following quip by H.von FOERSTER still remains significant: "Hard" sciences are hard because they study soft problems, and "Soft" sciences are soft because they study hard problems".

3485

SYSTEMS THEORY: Historical roots¹⁾

In his "Roots and branches" paper (2002, p. 417-428), K. BAUSCH explores the conceptual roots of **systems thinking**

He distinguishes:

- the 17th C. mechanical **model** (DESCARTES, - NEWTON, LEIBNIZ)
- the 19th C. organic model (SPENCER, MILLER, SUMNER)
- the early 20th C. **equilibrium** model (PARETO, PARSONS)
- the early 20th C. **homeostatic** model (CANON)
- the early and mid 20th C. **process** model (SIMMEL, MEAD, ALLPORT)

He also describes what he calls "new branches" i.e. the wide **variety** of more recent models that introduced significant new **approaches** in **systems theory**. Among many others he cites:

- HAKEN (**Synergetics**)
- PRIGOGINE (**Dissipative structuration**)
- EIGEN (Encapsulated **hypercycle**)
- CSANYI (**Emergence** of systems)
- KAUFFMAN (**Self- organization**)
- HABERMAS (Communication **action**)
- MATURANA and VARELA (**Autopoiesis**)
- WARFIELD (**Generic design**)
- FLOOD and JACKSON (**Critical systems thinking**)
- BICKERTON (**Language and representation**)
- LUHMANN (Systemic **process**)
- BANATHY and CHRISTAKIS (**Social systems design**)
- CHECKLAND (**Soft systems methodology**)
- GLEICK (**Chaos**) (in fact introduced by E. LORENZ)

Other angles have also been explored by Deborah HAMMOND (2002, p. 429-440) and Ch. FRANÇOIS (1999, 2000)

These various essays could become useful **inputs** for a more integrated and complete history of Systems thinking, still to be written

3486

SYSTEMS THEORY (Liberating)¹⁾

R.L. FLOOD in his work published under this title (1990), argues that Systems theory must be "liberating", i.e. reveal lost or suppressed **knowledges** in general, and even in Systems theory itself. This is related to the **dominance** of restrictive scientific and cultural **paradigms**, many times manifested through power relations and ideological biases.

The problem is obviously to avoid replacing some types of biases and power politics (not only present in politics) by others. Systems theory should be carefully watched over by systemists and non-systemists in order to avoid such risks. We would have to undertake a serious inquiry about the systemic **significance** of **coercion**, power abuse and ideologies.

See: "**Societal order parameters**".

3487

SYSTEMS THINKING (Critical)^{1) - 2)}

M.C. JACKSON, who introduces this concept, describes as follows the "five pillars" on which it is built:

- **Critical awareness**, which "... concerns **understanding** the strengths and weaknesses and the theoretical underpinnings of available **systems methods**, techniques and **methodologies**. Critical systems thinking is relentless in its pursuit of appropriate means of interrogation and in using these on the various **systems approaches**... Another form of critical awareness comes from closely examining the assumptions and **values** entering into actually existing **systems designs** or any proposals for a **systems design**"...
- **Social awareness** which "... should make users of **systems methodologies** contemplate the consequences of the use of the employed approach... Social awareness also involve recognizing that there are certain organizational and societal pressures which lead to certain **systems theories** and **methodologies** being popular for guiding interventions at particular times".
- **Complementarism at the methodological level**: "This requires a **methodology** (or perhaps a **meta-methodology**) which respects all of the other features of critical systems thinking" (FLOOD and JACKSON attempt to create such a **meta-methodology**, called "**Total System Intervention**" - 1991a).
- **Complementarism at the theoretical level**: "This requires an equal commitment to the complementary and informed development of all varieties of **systems approach**..."

Further, the claim of any one theoretical rationality, whether **functionalist**, **structuralist**, interpretive or emancipatory, to absorb all others, should be resisted"

- **Human emancipation**, seeking "... to achieve for all individuals the maximum **development** of their potential" (JACKSON, 1993, p.124-5)

These views, while somewhat ideologically tainted, are certainly important in order to avoid... ideological distortions in name of **systems thinking**.

For a quite complete **description** of Critical Systems Thinking see Chapter 7 in M.C. JACKSON (1992, p.183-212)

3488

SYSTEMS THINKING: Some critical appraisals¹⁾²⁾³⁾

In his well known essay on "The Rise of Systems Theory" (1978), R. LILIENFELD was very skeptical about the practical use of **systems theory**. He wrote: "No evidence that systems

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

theory has been used to achieve the **solution** of any substantive problem in any field whatsoever has appeared" (p. 192)

LILIENFELD critique was directed obviously at those scientists and technicians who thought that systems theory offered a cheap short cut for the solution of specific problems in specialized trades: a kind of **magic bullet** to avoid slow and painstaking research in the traditional way

He did however miss the real point, which is that systems's **concepts** and **models** offer the base for

1- a **transdisciplinary language** that fosters the capacity of reciprocal understanding between specialists

2- a needed complement for an integrated view of **complex systems**, as they exist and maintain themselves in their **environment**

F. CAPRA gives the following examples related to this second aspect: "It could be argued even then that the understanding of living **organisms** as energetically open but organizationally closed systems, the recognition of **feedbacks** as the essential **mechanisms** of **homeostasis**, and the cybernetic **models** of neural **processes**- to name just three examples that were well established at the time- represented major advances in the scientific understanding of life" (1997, p. 78)

In fact, traditional research in specialized area are complemented by systemic thinking

The necessarily **reductionist** research in specific **processes** (as for ex. the workings of enzymes) are in no way contradictory to a global view of the **living system**

The **part** becomes integrated in the **whole**, but must still be also researched as a part in itself

3489

SYSTEMS TYPES ¹⁾

J. SUTHERLAND distinguishes the following types of systems:

"1) **Deterministic**: No significant relational or structural **changes** through **time**. **State** alterations are negligible.

"2) **Moderately stochastic**: Some significant **changes** in coefficient and **parameter** values, but invariant basic structural and relational properties.

"3) **Severely stochastic**: Significant relational and some structural (i.e. **state-variable**) changes through **time**, where relational **changes** are reasonably well contained and where structural **changes** are **periodic** (replicative) or are drawn from a limited population of **state-variables** (determinant **array**).

"4) **Indeterminate**: Significant structural **change** through **time**, such that the **state-variables** or major determinants cannot be preassigned except partially and probabilistically;

both causal and structural properties either empirically inaccessible or unallegorizable; **state-changes** independent of prior **states**" (1973, p.146).

We should now (1992) add the **chaotic** type, which covers partially the three last types proposed by SUTHERLAND and introduces an apparently "**stochastic determinism**".

Another basic array of systems types, are, in the words of G. BROEKSTRA: "... the three **levels** of inquiry and description as distinguished by PRIGOGINE in physics: reversible classical or Newtonian **mechanical systems**, **irreversible equilibrium systems** or systems near **equilibrium** as dealt with by **classical thermodynamics**, and **nonequilibrium systems** of the kind called "coherent, evolving systems" or **dissipative structures**" (1993, p.74).

E. JANTSCH (1975, p.69 hereafter) and later on B. BANATHY (1988), in a somewhat modified form, offered the following classification of **human systems**:

"Rigidly **controlled systems** pursue prescribed operational targets in prescribed ways for attaining them (Examples: factories, bureaucracies)

"**Deterministic systems** pursue prescribed operational targets but select between various ways and **inputs** for attaining them (Examples: vertically organized production lines in industry, bringing into play various **sets** of material and nonmaterial **resources** and in various sequences)

"**Purposive systems** pursue prescribed strategic **goals** or multigoal **patterns**, but select the corresponding operational targets (and the ways for attaining the latter) (Examples: Industry developing various and possible innovative product lines, or diversifying in products and services under **function-oriented** headings such as power generation, transmission, distribution and utilization, or food production, processing and distribution)

"**Heuristic systems** select their **goals** or multigoal **patterns** flexibly within the **framework** of a prescribed overall **policy** (Examples: Industry developing new functional foci such as **environment**, or education; universities setting up **interdisciplinary** programs)

"**Purposeful systems** formulate and select **policies** in the light of the long-range outcomes (system **states**) of their own and their **environment's** potential **dynamics**. (Examples: New institutional **roles** for business, e.g. planner for society, or for higher education, e.g., education for self-renewal; **ecosystemic** view of world **dynamics** and **policies** geared to **stability** rather than **growth**, etc.)

JANTSCH states: "The above classification is of general validity and may be applied to **human systems** of all **sizes** and **scopes**. (Ibid) → "**Systems (Basic classes of)**".

T

3490

TAKE-OVER LAW ^{1) - 4)}

The superseding of an **evolutionary cycle** by another one.

This notion is introduced by D. DUBOIS and is related to the replacement of older vegetal and animal groups by new ones, with more complex features in their biological **organization** (1990, p.134).

This is also the case for man as a species and, possibly, is now becoming a characteristic of successive **levels** of **complexity** in **socio-systems**.

3491

TAMPERING ¹⁾

An inconvenient way to interfere with the basic **parameters** which govern "both the transient and **asymptotic behaviors** in an **autonomous system**" (Adapted from G. KLIR, 1993, p. 21).

KLIR states: "It is absolutely essential... that the **time-dependent inputs**, or forcings, do not change **autonomous dynamics** in any way" (p.21).

Tampering is frequently a result of an insufficient **knowledge** or **understanding** of **initial conditions** and **environmental constraints** rigging the system.

3492

TASK ALLOCATION ^{1) - 4)}

"The global **process** by which a **group, organization** or **society** assesses its current needs and "assigns" a certain number of members to perform specific tasks" (Adapted from D.M. GORDON, 1995, p.50).

D.M. GORDON found that, in insect societies, task allocation is a "**distributed process**", each individual being able to "perform any of a number of tasks", according to local and temporal circumstances. This seems to result from an **interactive perception** of global **environmental situations**. The introduction by GORDON of external **disturbances** in an ant nest increased or decreased the number of individuals performing some specific tasks, as for instance nest maintenance or foraging (Ibid).

More or less automatic task allocation seems also to be at work in human **groups**:

1) at a global **level**, regulating the number of individuals in each trade, compensating - with some **time lag** - for excess or lack of some kinds of professionals.

2) at a local **level**, for example increasing the presence and **activity** of some types of individuals in case of a disaster.

Task allocation is possibly a generic property of active **networks**, related to reciprocal sensing between **elements** and global fluctuating **stability** (as in ASHBY's **homeostat**, or through the action of **synaptic weights**).

3493

TAUTOLOGY ³⁾

A redundant proposition or "A proposition which repeats the same idea in other terms" (E. SCHWARZ, 1993, P.13)

→ **Structural differential**

This is the classical philosophical **meaning** of the word. In SCHWARZ's words: "According to **context**, a tautology can be no more than a repetition or triviality that does not add anything to which is known... or on the contrary a **self-referential** proposition"

Indeed, the general **concept** of **autopoiesis** introduces an interesting new shade of **meaning**, related to the **self-reproduction** or **organizational closure** of **autopoietic systems**.

E. SCHWARZ describes it in this case as "... a foundational **self-referential** proposition, which is fundamental or basic, as for example the **identity** principle in classical **logic**: $A=A$, what is, is" (1993, p.13)

But... is this meaningful, or meaningless?

3494

TAXON MEMORY ³⁾⁵⁾

Data storage in the **brain** through ordered listing of related items.

R. NUMELLA CAINE and M. CAINE explain: "These memories consist of items that do not depend on a specific physical **context**. They include prototypes or **categories** that represent a generic item, such as bird or house or dog; the **contents** of **categories**, such as types of trees or cars; and **routines** and **procedures**, such as driving" (1994, p. 42)

The basic features of taxon memory are:

"1. **Information** in taxon memories are placed there through practice and rehearsal...

"2. Taxon **learning** is linked to extrinsic **motivation** and is powerfully motivated by external reward and punishment...

This is evident when students memorize for tests instead of seeking to understand ideas...

"3. Our taxon memories are physiologically "set" in a way that makes them quite resistant to **change**, as anyone who has tried to change a **habit** knows...

"4. Items in our taxon systems are relatively isolated. That is they exist as stable **entities**, such as driving a car and memorizing phone numbers, that can be called on and used in a fairly predictable manner. The items are only relatively isolated because they can be highly organized and do interact with other items stored in **memory** so that they can be called on as needed during ongoing **events**...

"5. Much of what we store in taxon systems is not initially meaningful. What matters to us is that the **information** can be recalled or the skills used, on demand, irrespective of the **meaning**..."

The authors credit J. O'KEEFE and L. NADEL (1978) for the introduction of the **concept** of so-called "taxon memory systems".

→ **Structural differential**

3495

TAXONOMIES of systems ¹⁾

Systems and their **components** have been classified from different viewpoints by a number of systemists, as for example K. BOULDING (1956), J.G. MILLER (1978) and G. KLIR (1969) in the States and E. JANTSCH (1975), J.L. LE MOIGNE (1977), B. WALLISER (1977) and J. LE-SOURNE (1976) in Europe. P. VOLTES BOU (of Barcelona) (1978) and B. WALLISER (1977) have also proposed a **classification** of **models** types.

L. TRONCALE intended a general classification of cybernetic and systemic **isomorphies** (1985).

As each pursues some specific finality, none of these taxonomies is exclusive of the others, while some are in part coincident. None should be considered as the ultimate truth, as they are merely kind of general **maps** of a very complex **field** and, moreover tend as any classification, to be somewhat procustean: cutting or adding characteristics to suit the general idea. In any case, they are useful and a practical necessity.

CHANG-GEN-BAHG more recently tried to establish a taxonomy of systems theories and a "system of systems sciences", including "**systemology**, **systems methodology** and **systems engineering**" (1990, p.79-107).

→ "**Systems (Basic classes of)**".

3496

TEAM SYNTEGRITY ²⁾

"A proprietary technology developed by Stafford BEER whereby 30 people come together to explore a subject of interest to the **group**" (S. BEER, 1994, p.282)

BEER comments: "The Team Syntegrity technology uses the form of the Icosahedron as the basis for organizing and scheduling the activities and discussions of 30 people around 12 major topics".

BEER derives the term "Syntegration" to name "an event in which the Team Syntegrity protocol is applied" (Ibid)

→ J.van Gigch interesting commentary (1996, p.73-5)

3497

TECHNICAL MACROSYSTEM ^{1) - 4)}

Any system which implies the simultaneous, interconnected and **synergetic** use of different technologies.

Examples are electrical interconnected **networks**, telecommunications systems, railways **networks**, worldwide airlines and aerial traffic **control systems**.

An important characteristic of these systems is the permanent monitoring and **control** of the constantly changing **state** of the **network** and of its **elements**, through an uninterrupted **flow** of **information**.

Technical macro-systems include of course a considerable number of human participants (the **agents** of the technical **management**). They tend to evolve toward increasing **complexity** and some may undergo **phases** of **instability**.

They may also show a growing resistance to **change** becoming **hypercomplex**.

According to A. GRAS, the western way of using techniques based on massive **energy** use is leading **mankind** toward a **network** of evermore expanding and integrated socio-technical macrosystems (TMS) (1993).

This is consonant with **structuration** and **emergence** through energetic **dissipation** as established experimentally by BÉNARD and generalized as a **thermodynamic non-equilibrium process** by PRIGOGINE.

It remains to be seen if these TMS are already acquiring their definitive **structure**, or if the possible future exhaust of mega and macro fossil **energy sources** could oblige them to a global reorganization, based for example in numerous smaller local **energy sources**.

3498

TECHNOCENTRISM ^{1) - 4)}

The supremacy of technicians and technical views in the **management** of a **human system** (enterprise or **organization**).

Technocentrism easily leads to the "let us fix it right now" mentality, leading in turn to a vicious circle of **problems**-generating solutions. Technique, in itself useful or indispensable, should be evaluated within the general **frame of reference** of global **optimization**, and global **constraints**.

→ **Ethnocentrism**

3499

TECHNOLOGICAL DETERMINISM ^{1) - 4)}

"The belief that technology develops by its own laws, that it realizes its own potential, limited only by the material **resources** available, and must therefore be regarded as an **autonomous system** controlling and ultimately permeating all other **subsystems** of society" (K. KRIPPENDORFF, 1986, p.74).

KRIPPENDORFF himself evaluates this belief: "Evidence for the first proposition is largely taken from the natural history of technology, its progressive character and the co-occurrence of independent inventions. Evidence for the second proposition stems from the unwarranted

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

generalization that everything that is invented is ultimately installed and ignores human playfulness, individual and collective interests and man's cognitive limitations" (Ibid).

It remains however obvious that the massive uses of technology deeply modifies human individual and collective **behavior**, generally accelerating and densifying **interactions** (Good examples are the car and the telephone, and now, the internet). Such **changes** could eventually lead to a **negative feedback** due to general **overburdening** of **eco-** and **sociosystems**.

3500

TECHNOLOGY ¹⁾ - 4)

The body of **knowledge**, **methods** and tools that allows man to growingly adapt his **environment** to his needs.

While some superior vertebrates invented some primitive techniques, it is man who made technology into an active and overwhelming **transformation** power of his societies, and their **relations** to their **environment**.

This **process** is presently accelerating in an explosive way, putting the whole mankind-planet system in a growing **instability** stance.

Systemics should urgently investigate this **runaway phenomenon**.

→ **Evolutive acceleration**

3501

TECHNOLOGY ASSESSMENT ¹⁾ - 4) - 5)

The **evaluation** of possible future **effects** of some new technology.

According to the UNESCO-UNEP Glossary it uses: "**Methods** and **processes** of projecting, evaluating and predicting possible **short** and **long range** physical, social, economic, and ecological benefits and **costs**, including negative **side effects** and impacts, of introducing a particular technology in general or for a given area of the **environment**" (1983, p.27).

Unfortunately, the growing number of catastrophes from technological origin shows that technology assessment is still much wanting. This is obviously because it is nearly always practiced from an ad hoc and partialized viewpoint.

Two important causes of such situation seem to be:

- Technology assessment cannot be partialized (or **underconceptualized**, in J. WARFIELD's terminology), if it is to be really reliable. Most recent disasters show that, in practice, dangerous or questionable technologies were only assessed by specialists, using narrow, short sighted and **short term usefulness criteria** (C. FRANÇOIS, 1989, p.1101-11).
- Technology assessment has a totally neglected the ethical aspects, and frequently the social ones. This is due to the presently overpowering (and sometimes downright cynical) utilitaristic bias in the dominant cul-

ture. A result is that the possible problems, even when suspected, are frequently and artfully concealed.

In conclusion, technological assessment should be grounded on:

- a) systemic concepts and **methods** to be used to globally evaluate modifications to **complex systems**, and
- b) a **systemic ethics**, concerned with present and future human rights and responsibilities as well as with **ecological** future.

3502

TECHNOLOGY CREATION (Ethics of)

→ **Ethics of technology creation**

3503

TECHNOLOGY (Sustainable) ¹⁾

N. GEORGESCU ROEGEN observes: "Not all technologies... are viable. A technology is viable if and only if the corresponding production **processes** are mutually self-sustaining and also produce a net product capable of maintaining a tolerable size of **population**."

"The test of the **viability** of a technology must be applied to a **steady state**" (1982, p.314).

Sustainable technology is obviously related to **homeostasis** and **autopoiesis**.

3504

TECHNOSPHERE ¹⁾⁴⁾

The growingly interconnected set of man-made **artifacts**

It includes for example factories, administrative buildings, schools, etc, but also mobile artifacts like vehicles and aircrafts and the **network** of roads, railways tracks, airfields, radio and television **links**, etc...needed for **communication** in general

The technosphere is now becoming globally integrated on the planetary **level**

It is steadily evolving under the impact of scientific discoveries and technical innovation. It is also becoming evermore dependent of a massive and permanent supply of cheap **energy**. Such a dependence could imply the need for deep global mutations in the **long-term** future

Moreover, the harmonious **integration** of the technosphere within the planetary **ecosystem** (**ecosphere**) is still an unresolved problem

Finally, the ever expanding technosphere generates deep economic and socio-cultural changes, many of them unforeseen and unplanned

The future **evolution** or final **stabilization** of the world technosphere remains an open **issue**.

3505

TEKTOLOGY ¹⁾

The basic concept of possible systemic **laws** was enuniated by A.A. BOGDANOV in his treatise: "A Universal Organizational Science (Tektoology)" (Moscow, Leningrad, 1925-1929, in Russian).

I. BLAUBERG, V. SADOVSKY and E. YUDIN write: "The basic assumption of tektology as formulated by BOGDANOV is that the **laws** of **organization** of systems are the same for all possible **objects**, both material and ideal, thereby making a generalized formulation of these **laws** feasible: "**Structural relations** can be generalized in the form of schemata just as rigorous as these describing quantitative **relations** in mathematics, and this can serve as the basis for solving problems of **organization** with the aid of **methods** similar to mathematical ones" (1977, p.26).

A. BOGDANOV himself thus defined the program of tektology: "Tektoology must clarify the **modes** of **organization** that are perceived to exist in nature and human **activity**; then it must generalize and systematize these **modes**; further, it must explain them, that is, propose abstract schemes of their tendencies and **laws**; finally, based on these schemes, determine the direction of **organizational methods** and their role in the universal **process**. This general plan is similar to the plan of any natural science; but the objectives of tektology are basically different. Tektoology deals with **organizational** experiences not of this or that specialized field, but of all these fields together. In other words, tektology embraces the subject matter of all other sciences, and of all human experience giving rise to these sciences, but only from the aspect of **method**: that is, it is interested only in the **mode** of **organization** of this subject matter" (1980, p.III).

G. GORELIK, who translated BOGDANOV's book to English, comments: "BOGDANOV insists that the question of **organization** should be considered on a universal scale, for in absence of such an integral approach its solution is "... impossible, because a **part** torn out from the **whole** cannot be made the **whole**, nor can it be understood apart from the **whole**" (Ibid).

Further along, BOGDANOV observes: "It is easy to see that there is a special **correlation** and a deep kinship between **mathematics** and tektology. The **laws** of **mathematics** do not refer to this or that **field** of the **phenomena** of nature, as **laws** of other special sciences do, but to all and any **phenomenon**..." (Ibid., p.46).

In a bout of - possibly protective - marxist activism, BOGDANOV also stated: "For tektology the unity of experience is not "discovered", but actively **created** by **organizational** means: "philosophers wanted to explain the world, but the main point is it change it" said the greater precursor of **organizational** science, Karl

MARX. The explanation of **organizational** forms and **methods** by **tektology** is directed not to a contemplation of their unity, but to a *practical mastery over them*" (Ibid, p.61).

That **tektology** or **systemics** may be used to try to *change* the world is a distinct possibility, but one which should be used with care and restraint, because even **systemic models** are merely *models*.

In any case, this all is clearly a blueprint for **systemics**, in 1922, nearly 30 years before L.von BERTALANFFY seminal paper in the British Journal for Philosophy of Science (1950).

The progressive incorporation within the systemic-cybernetic frame of numerous **isomorphic models** and **laws**, generalized from some specific discipline, has fully vindicated BOGDANOV's fundamental methodological claim.

3506

TELEOGENESIS¹⁾

"Goal formulation" as a property of systems able to generate their own **goals**.

N.A. COULTER Jr. proposed the concept of teleogenetic system, or teleogenetic **control** systems, which "have the capacity to generate their own **goal**" and "exhibit **goal-seeking behavior**", i.e. "searching for a **goal** to seek" (1968, p.85).

According to COULTER, such systems would have the following capabilities:

"1. **Teleological (goal-seeking) behavior**. It should be capable of controlling an **output** quantity in such a way that it conforms to a "**goal signal**"...

"2. **Teleogenesis (goal-formulation)**. It should be capable of proposing **goals** within the range of capability of its teleological **mechanism**.

"3. **Forecasting**. On the basis of sensed **data** about the controlled quality (in the absence of **action** by the teleogenetic system) it should be capable of predicting outcomes if a proposed **goal** is adopted by the system.

"4. **Evaluation**. In terms of **values** (either initially endowed or accumulated by "experience") it should be capable of assigning **worth-values** to the **forecast** outcome spectrum associated with each **goal**, and computing a global worth-function for the **decision process**.

"5. **Decision**. In accordance with some **decision** procedures, the system should be capable of selecting one of the proposed **goals** and committing the system to that **goal**" (p.85-6).

COULTER's proposal does not seem to have been further researched or applied, save quite recently by G.G. JAROS in South Africa (1994, p.5) (see: **Teleos; teleonics**). However, its relation with the **perceptron** and the more recent **self-organizing networks** is obvious.

3507

TELEOLOGICAL CONCEPTS^{1) - 3)}

The general idea of **self-organizing goal-seeking systems**, able to pursue self-defined **goals**, is circulating around in **systemics**, practically since its beginnings. It has been in various cases cloaked in greek apparel (Telos = **goal**, etc ...), a fact that did not necessarily make it more accessible and clearer.

The first source was possibly the Golem, which (or who?) was **goal-seeking**, but not much **self-organizing**. But the model is the human being him/herself, in search for his/her deepest **understanding**.

We may approach the goal concept through the general **synergetic** one of **order-parameter**, "the **macroscopic structure** or **field** emergent out of **interactions** at the more **microscopic level**" or "a **macroscopic** collective **field**, **emergent** at **critical points** out of myriad **interactions** at the **microlevel**", in K DE GREENE words (1994, p.12). Simultaneously, various **networks models** and also experimental devices are now exploring this field.

Hereafter, some teleo-related concepts and **models**.

3508

TELEOLOGICAL EQUATIONS²⁾

Equations in which "**changes**" in the system are expressed not in terms of actual conditions, but primarily in terms of the distance between the present **state** of the system and its final **state**" (I. BLAUBERG et al., 1977, p.51).

BLAUBERG et al. explain: "In other words, the systems under study are described in such a way as to make it appear that the actual **changes** depend upon a final **state** to be attained later" (According to L.von BERTALANFFY, 1971, p.75-80; 139-141).

To establish such equations for any **complex system** seems to be a very tall order.

Obviously any final **state** is necessarily hypothetical in some sense, as well as the precise moment in which it will be reached. It can be stated only within the limits of the supposed or postulated **goal** of the system, when this **goal** can be understood from some characteristics of the system.

A global aphorism like STAFFORD BEER's "Death is **equifinal**", leaves us still quite far from a set of teleological equations that should predict the future **transformations** of a concrete **living system**.

3509

TELEOLOGICAL EXPLANATIONS³⁾

W.R. ASHBY rejects teleological explanations for **behavior**: "It will be assumed throughout that a machine or an animal behaved in a certain way at a certain moment because its physical and chemical nature at that moment allowed it no other **action**" (1960, p.9).

This smacks of **reductionism**. It is really very difficult to explain "intentionality", even in animals. It could be tentatively considered as a **convergence phenomenon** in systems equipped to treat **information**.

However, it is not possible to ignore the following comment by ASHBY: "Never will we use the explanation that the action is performed because it will later be advantageous to the animal. Any such explanation would, of course, involve a circular argument" (1960, p.9).

Still, could the memorized effects of successful previous **feedbacks** not constitute a satisfactory base for the repetition of useful **sequences**?

3510

TELEOLOGY^{1) - 2) - 3)}

"... directed **behavior**" (L.von BERTALANFFY, 1956, p.7).

J.Z. YOUNG describes teleology as: "The study of **goals**, ends or **purposes**" (1974, p.299)

Contrarywise, for D. BOHM and F.D. PEAT: "Put in the form of a **metaphor**: **Mechanism** is teleology" (1977, p.43).

This statement implies the meaning that any **mechanism**, being basically **deterministic**, seems to convey the inevitability of defined future **states**. In this sense, teleology is implied in Newtonian and Laplacian mechanics, without any needed reference to **purpose**, even if the 18th Century illuminists viewed God as the "supreme mechanic and watchmaker".

This is somehow confirmed by BERTALANFFY's statement that teleological **behavior** "... is a form of **behavior** which can well be defined in scientific terms and for which the necessary conditions and possible **mechanisms** can be indicated" (Ibid).

The word "purpose" in YOUNG's definition however opens the door to a wide discussion, as immediately obvious in this comment by O. YOUNG: "... teleology may be taken analytically as a subheading of the concept of **goal**..." (1964, p.79).

Now, what means "directed": directed by what?

And what is a "**goal**"? Is it something merely implicit within the **behavior** of a non-volitive system? And when dare we say that a system is volitive? And, even, what is exactly "volition"?

Obviously, teleology is in many authors heavily contaminated by anthropomorphism.

Another conceptual muddle was cleared by A. ROSENBLUTH, N. WIENER and J. BIGELOW already in 1943: "Teleology has been discredited chiefly because it was defined to imply a cause subsequent in **time** to a given effect. When this aspect of teleology was dismissed, however, the associated recognition of the importance of **purpose** was also unfortunately discarded. Since we consider purposefulness a

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

concept necessary for the **understanding** of certain modes of **behavior** we suggest that a teleological study is useful if it avoids problems of **causality** and concerns itself merely with an investigation on **purpose**. We have restricted the connotation of teleological **behavior** by applying this designation only to purposeful **reactions** which are controlled by the **error** of the **reaction** – i.e., by the difference between the **state** of the behaving **object** at any time and the final **state** interpreted as the **purpose**".

The final **state** is, of course, a *presently desired future state*, inscribed as a reference within the **control structure** of the system. There is thus no future **action** on the present and any paradox is avoided.

The authors add: "Teleological **behavior** thus becomes synonymous with **behavior** controlled by **negative feedback**... The concept of teleology shares only one thing with the concept of **causality**: a **time axis**" (1943, p.24).

As noted by R.L. ACKOFF, this introduced a deep conceptual mutation: "... in mechanistic thinking, **behavior** is identifying what caused it, never its **effect**. In teleological thinking, **behavior** can be explained either by what produced it, or by what it intended to produce... Study of the **functions**, **goals**, and **purposes** of individuals and **groups** has yielded a greater ability to evaluate and improve their **performance** than mechanistically research did" (1991, p.329).

Any **feedback controlled** teleological **behavior** needs, in cybernetic terms, three **components**: a **reference value** (expressing the **purpose** stated into the system), a **sensory function** (needed to measure eventual **differences**) and an **effector function** (needed to make the **control** effective). These are the basic **parts** of any **regulator**.

It should be observed that at least one of the founding fathers of cybernetics, W.R. ASHBY did not accept teleology: "Our **purpose** is to explain the origin of **behavior** which *appears* to be teleologically directed" (1960, p.9).

One wonders which "physical and chemical" factors (see former entry) induced in ASHBY the "**purpose**" to give a purely **deterministic** explanation of **purposive behavior**.

It would seem that teleological views are quite acceptable, for example within the **organizational closure frame** of **autopoiesis**, or P. VENDRYES' concept of **autonomy**, as the capacity of a system to make a **decision** about its **behavior** at any present instant, either by repeating a formerly successful **decision**, or in function of a *presently* (or even formerly) defined **goal** to be reached in the future.

Even ASHBY's own **homeostat seeks(!)** an **equilibrium** point through successive **adjustments**.

The split between the two viewpoints is probably a **semantic** problem that could be summed up as follows: How *purposeless* should a **purpose**, to be admitted as a spontaneously formed **behavioral regulator** in a system.

The final way to get out of this tangle is probably through R. ROSEN's observation that a system may contain a *projective* or **predictive model** (from the pure physiological **level** to the cerebral-mental one) and develop an **anticipatory behavior**, in accordance with what it can predict about possible or probable future **situations**, be these predictions correct or not.

3511

TELEON^{1) - 2) - 4)}

"A goal-directed **process** unit, which stretch over several **levels** and incorporate numerous living and non-living **subsystems**".

This concept has been introduced by G.G. JAROS, of South Africa, who states that it "has been applied to the study of **complex systems** in the diverse **fields** of **education**, social **governance**, business **organization**, technology **assessment**, psychology, health care and music theory" (1994, p.5).

JAROS distinguishes endoteleons, "which connect an upper (outer) **level** to a lower (inner) **level**" and exoteleons "which are directed at the higher (outer) **levels**. At each **level** bundles of both kinds of teleons combine to form doublets. Examples of doublets are the **cells**, individuals, families, **organizations**, **communities** and **societies**" (Ibid).

The similarity with MILLER's **levels** is obvious. But JAROS states: "**Cells**, humans and **organizations** are the result of their **processes** and not vice versa" (Ibid). This could provide the connection with SABELLI's **Process theory**. JAROS, moreover, seems to consider his teleons as **translevel connective** units, not merely **structural-functional** ones at specific **levels**.

In a more recent paper G. JAROS & E. DOS-TAL replace the word "teleon" with the word "*process*" in italics, to differentiate it from the common use of the word.

They define this new "*process*" as "a spatio-temporal arrangement of **actions** forming in an autonomous, **self-regulated** system, as opposed to a simple, non regulated temporal **sequence of actions** the everyday usage of the word "process" tend to indicate"(1999, p. 199)

3512

TELEONICS^{1) - 3)}

"A **systems approach** ... which focuses primarily on the **processes** that characterize **living systems**, rather than on the **levels** and **subsystems** of which they consist".

This approach, developed by G.G. JAROS, attenuates the **dichotomy** between **levels** and the **whole** in systems. It seems more concerned with vertical unity than with horizontal **strata**.

According to JAROS: "In Teleonics, one does not speak of **interaction** between **entities**, but **interaction** between **processes**. By definition, **processes** have some kind of **goal**, end point or destination, which may or may not be intentionally determined. We refer to this "go-for-it" quality as **goal-relatedness**, which can include **goal-seeking** as well as **goal-directed behavior**" (Contribution to the "Primer Handbook", work in progress, 1996)(Th. MANDEL)

It is in any case difficult to conceive **processes** that would not be proper to some **entity**, or entities without **processes**. However, the **concept of process** conveys better the **understanding** of a **time dimension** in systems.

It should be observed that N.A. COULTER Jr., himself inspired by J.E. GIBSON's "**hierarchy** of automatic **control**" proposed in 1968 a "theory of **teleogenetic control** systems" based on **control** systems able "to generate their own **goals**" and "exhibiting "**goal seeking behavior**... as a special **mode of operation**" (1968, p.85).

3513

TELEONOMY^{1) - 3)}

A system's **behavior** characterized by any non-purposeful end-directed **process**.

R. VALLÉE writes: "A **dynamic system** is teleonomic if it evolves *as if* it would aim at a **goal**. It is the case of **cybernetic systems** whose present **state** tends by way of a **negative feedback** to close in toward a **state** to be reached" (1995, p.17).

"The word teleonomy was invented in the fifties by PITTENDRIGH to replace **teleology** in order to get rid of finalism in biology... the difference being that in one case (**teleology**) one deals with **purposeful** end-directed **processes** governed by an "intelligent, designing mind", while in teleonomy one is looking for non-purposeful end-directed **processes**" (H. ATLAN, 1989, p.240).

Still, one wonders about the real **meaning** of an "end-directed **process**" which is not "purposeful", ...or how do we define "**purpose**", "**goal**", "**end**" and the like in such a way as to avoid **ambiguities**.

Moreover, PITTENDRIGH's good intentions did finally not suppressed the confusion: in 1990 still, M. LIU can write: "The notion of **program** permits to escape from this difficulty (i.e.: anthropomorphism), and to conceive teleonomy as a property of life" (p.274), which is alright ... if humans are not considered as **living systems**!

Fortunately, in his Systemic Glossary (in french) E. SCHWARZ gives the following explanations: Teleonomy is "the directional property of the logical **organization** of a system (=directionality) such as any change seems to aim at a future **goal** (rule in an **homeostatic system**, **self-reproduction** in an **autopoietic system**, existence of a **tropism**, a need, a desire, an intention, a goal, a **purpose**, etc...) The goal may even itself evolve in time. One could be tempted to oppose a causal system (whose present state is caused by its past) to a teleonomic system (whose present state seems to be conditioned by a goal). This would be erroneous, as the teleonomic property is itself causal, i.e. the result of the history of the teleonomic system"(1993, p. 13)

Another interesting view is J. MONOD's one, who considered the human central **nervous system** as the most teleonomic system that ever appeared. Its main characteristic is seemingly its **predictive** capacity which gives it the possibility to project in the present a more or less probable forecast of the future. This creates some possibility to control it. (J. MONOD, 1970)

It could be said finally that teleonomy as a concept mainly points to a peculiar link between past and future through a capacity of creating a directive **correlation** through a **feed-forward**. This could be called "teleonomic **coherence**".

→ **Finality; Purpose; Purpose in social systems; Retro-propagation approach**

3514

TELEOS: "Purpose, aim, goal or end" ¹⁾ - ³⁾

This is another neologism introduced by G.G. JAROS.

It seems useful, because it "de-anthropologizes" the value-laden concepts of **purpose**, etc... However, this was not necessarily JAROS intention. He states anyhow: "Any analysis of **teleons** should start with the identification of the teleos" (1994, p.5) ... which of course is relative to the views of the **observer**.

3515

TELESITIC BEHAVIOR ¹⁾

This expression has been proposed by L. THAYER as different from '**teleologic**'. It refers to: "... what man *can* do, even if we have no more evidence for that capacity than what a few men have achieved... The term is not entirely satisfactory, but we need some concept to account for the fact that men, unlike their fellow creatures, can undertake to become (socially, psychologically, etc.) what they *are not*" (1972, p.105).

Man, as a hypercomplex system, has many virtual possibilities that will normally remain unused, but could be waken up by some unexpected **stimulus**.

3516

TEMPLATE ¹⁾

A **pattern** that can be used for replicating some kind of **element**.

This is a systemic **isomorphy** for many types of stable **structures** bearing some specific **function**. Genes in living beings, or **values** and **norms** in **sociosystems**, are templates in their own field of action (L. TRONCALE).

But, how did the first template appear?

According to H. KUHN, it must have been caused by the emergence of repetitive **dissymmetries**, which may have been equivalent to **rules** in the development and self-stabilization of **automata** (1976).

Environmental influences, when permanent or repetitive, may act as templates. Examples are specific **gradients** of humidity or temperature, that may condition **behavior**, for instance of bees or ants.

→ **Symmetry breaking**

3517

TEMPO, PULSE AND RHYTHMS IN SYSTEMS

According to recent research, it appears that perception of time is **discontinuous**

Carolyn DRAKE, of CNRS, R. Descartes University in Paris, "believes that we sample the world roughly twice a second, checking on each sense to see if sounds or sights have changed. She goes on to suggest that we perceive the world best during these pulsed check-ups. It's how we filter out **information** that would otherwise overwhelm us" (T. GURA, p. 33, 2001)

Rhythm would thus be as much a result of internal tempo of our **nervous system**

→ **Rhythm; Time; Synchrony timer**

3518

TEMPORAL HIERARCHIES

→ **Hierarchies (Temporal)**

3519

TENSEGRITY

"The overall tensile **stresses** of the entire system" (S. BEER, 1994, p.13)

This neologism is a contraction of "Tensile (or tensional) integrity", an expression related to BUCKMINSTER FULLER's geometrical concept of the general conditions of **equilibrium** of complex **structures**, based on **structural relationships**.

BEER writes: "According to this, the **wholeness**, the **INTEGRITY** of the **structure** is guaranteed not by the local compressive **stresses** where structural members are joined together, but by the overall tensile **stresses** of the entire system" (p.13).

Tensegrity allows the redistribution of tensions within a **structure** submitted to deformations, provided each **element** in the **structure** (generally speaking struts and wires) can bear both tensions or compressions. Some **structures** of this type can even shift from one shape to another in reaction to external pressure, while still maintaining their general characteristics.

S. BEER relates tensegrity to the general notion of logical (or organizational) **closure**. He derived his concept of **Syntegrity**, as applied to human teams from the tensegrity **model**.

For more about tensegrity, see R. CONNELLY and Allen BACK (1998, p.142-151) and Martin BROOKES (1999, p.43-46).

3520

TENSION

→ **Stress**

3521

Tensor ²⁾⁵⁾

A generalized mathematical **function** for transforming a vector into another vector, irrespective of the **frames of references** used

Tensors are used to map **transformations** from one coordinate system into another

3522

TERM (Short-, Medium-, Long-) ¹⁾

Different **time scales** in **processes**, **rhythms** and **phenomena**.

What short-, medium- and long- means must be clarified in each case. Geological **cycles** are obviously at a different **scale** than living beings, or meteorological **events**.

The really interesting aspects of different, but imbricated **time scales** are as follows:

- **Time** regularities can be observed in most **processes** at different **scales**. In **living systems**, **circadian rhythms** for example, are clearly distinct from seasonal ones, while both are inscribed within the long-term scale of life as a **whole**.
- Short-, medium- and long-term **rhythms** are more or less interconnected, because they correspond to interconnected **phenomena**. **Population cycles** of different species in predators-preys **relationships** may combine to induce a long-term global **cycle**. This also seems to be the case for the different economic and business **cycles**.
- Long-term cycles offer a limited predictive capability as to the progress of the medium and short term **cycles**. This seems to be related to **chaotic determinism**.

The whole subject deserves more intensive study.

See for example "Fractal scaling", "Frequency analysis", "Kondratiev cycle" and "Weierstrass equation".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3523

TERRITORY¹⁾

That part of **space** totally or partially controlled by a **living system**, an **ecosystem**, or a **socio-system**.

K. BOULDING, who discussed the concept of territoriality, wrote that: "It is relevant to the theory of **niche** and to the determinants of **niches**. Thus any **organization** in competition with others will find that its advantage in the **interaction** diminishes as it goes away from some kind of 'home base', so that at some point the advantages of any further expansion fall to zero. This is what I have called the "**boundary of equal advantage**" between two **organizations**, but the concept could easily be generalized. It is these **boundaries of equal advantage** which really define the **niches** of an **ecological system**. Economy has made an important contribution through **location** theory, especially in the work of LÖSCH (1944 and 1954), who demonstrated that, even if we start with **resources** and **population** distributed uniformly in the geographical **field**, the sheer pressures of maximizing **behavior** will force the **field** into **clusters** and **structures** and will indeed create what are in effect **niches** in what previously had been an uniform **field**" (1972, p.69-70).

It should be noted that the pioneering work in **location** theory was made by W. CHRISTALLER in 1923 (1933 and 1937).

→ **Hexagonal space filling, and possibly, fractals**

3524

TESSARACT¹⁾²⁾

A 3-dimensional representation of a 4-dimensional **construct**.

For a quite imperfect impression see a 2-dimensional representation under "**Hypercube architecture**".

3525

TESSELATION²⁾

The subdivision of **space** into a mosaic of regular or irregular shapes, completely covering the **space**.

Tessellations have been widely explored by the Dutch engraver M.C. ESCHER, and the English mathematician R. PENROSE.

They are useful in the study of **modes** of **space** occupation, which probably reflect underlying **fields** of forces, variously **constrained**. They suggest at times very odd **models** which surprisingly may be confirmed by observation, as in crystallography.

→ **See also: Hexagonal space filling**

3526

TEXT¹⁾

"Data with an inherent **pattern**, **structure** or **organization** through which the **meanings** are revealed".

This is a cybernetic meaning for "text", as given by K. KRIPPENDORFF (1986, p.75).

3527

THEMATIC ATTRACTOR¹⁾⁵⁾

A focal **point** around which we center our life experiences and expectations.

It seems that no human being escapes from such "global organizers" in their life. They could also be called "global **behavioral polarizers**".

Some examples are: the lust for power in politicians; the lust for money in businessmen; the fascination with some specific aspect of the "unknown" in high level scientific innovators - or, in the past, geographical explorers; the exploration of pictorial **forms** for painters, or musical ones for composers; etc...

Nobody devoid of a powerful thematic attractor is seemingly able to become a leader or creator in his/her field, nor even a significant achiever in life.

3528

THEORIES as DEDUCTIVE SYSTEMS³⁾

W. ACAR elaborates on R.L. ACKOFF's **understanding** of what is a theory in the following definition (1988, p.172):

"Theory: a *deductive* system comprising

- 1) a **set** of defined and undefined concepts denoted as the "symbolism" or **language** of the theory
- 2) an assumptional or axiomatic foundation denoted as the "postulates" or "hypotheses" on which the theory rests
- 3) A **set** of implicit or explicit formation or **transformation rules**, called the "logic" of the theory
- 4) A **set** of deduced propositions called the "theorems", "**laws**", or "results" of the theory
- 5) A **set** of instances of applications of the results of theorems, known as "**facts**", "consequences" or "implications" of the theory".

ACAR comments: "We now perceive very clearly what the Singerian philosophical school has forecasted, the relativity of our **knowledge** base and the increased use we make of **models**. Both basic and applied research make an extensive use of the **modelling activity**" (p.173).

Deductive theory are basically **algorithmic**. When some new **observations** or **concepts** cannot be reduced to the **structure** of existing theory, this must be modified or abandoned.

It is also clear that a theory is a *conceptual system*, with general characteristics and a kind of conceptual **closure** that mirrors **organizational closure** in living systems.

3529

THEORY ? (What is a)²⁾³⁾

P. BAK writes: "According to one of the most fundamental principles of science, a theory is a statement about some **phenomenon** in nature that in principle can be confronted with **reality** and possibly falsified" (1996, p. 162)

The presence of the word "**reality**" in this sentence puts us on shaky ground (See: "**Ontological Skepticism or Agnosticism**").

BAK pursues, however: "The **description** can be either verbal or mathematical. In physics, we use the **language of mathematics** to express our theories. To confront the theory with **reality**, we solve equations and compare with experiments" (Ibid). One problem with this is that experiments are constructed by the experimenter, i.e. "**reality**" is "doctored" (The famous condition: "**et ceteris paribus**", which defines which **context** is to be neglected as - hypothetically - not relevant). Moreover, theory may subtly influence the **goal**, forms and **interpretations** of the experience.

Anyhow, let us accept BAK's view: "If there is disagreement, we return to the drawing board"

He immediately adds: "When theories are expressed verbally in terms of much less precise **languages**, the confrontation with **facts** is much more cumbersome and leaves space for endless discussions among experts as to what constitutes the better **description**. Sometimes the experimental **observation** itself, without any condensation in more general principles, is viewed as a theory" (Ibid)

Finally, there is no unequivocal way to unload the ? out of our inquiry.

3530

THEORY (Minimal axiomatics of any general)³⁾

D. Mc NEIL describes as follows the minimal axiomatics of any would be general theory:

"1. There is a constitutive core of **concepts** which interrelate mutually with one another at the center of the theory, more in the manner of a **voluntary loop** than of a closed capsule or an aggregate **cluster**.

"2. There is a mutually productive, even a **generative, connection** between the central concepts and the peripheral ones where theory is reduced to practice.

"3. The core of the theory is the minimum algorithmic compression from which **phenomena** described by the theory can be reproduced.

"4. The core of concepts is irreducible in the sense that, although equivalent concepts may be substituted, no central concept can be removed without altering the scope and productivity of the theory or even render it meaningless.

"5. Two or more of the core concepts are complementary in some sense to another.

"6. The central concepts are well-defined, and their connotations harmonize insofar as possible with similar concepts of ordinary enlightened discourse.

"7. The central concepts are expressed at a uniform level of discourse, and different levels of discourse are clearly distinguished and used consistently;

"8. The more general theory relates to less general theories and to special cases through a correspondence principle which acts as a confirmation and a guarantor of the consistency of the more particular theories and of their applications.

"9. Whether explicitly or by implication, the theory describes dynamical fluxes having contours which trace relatively closed loops as well as relatively open links.

"10. Whether in the assumptions or in the expression of the formulation, there are invariants which provide standards for measures.

"11. The theories describe phenomena in the frame of reference of a conceptual space, thus implicitly relating the observer with the phenomena observed" (1993a, p.8).

To establish this list, Mc NEIL inspired himself from MAXWELL's electromagnetic theory and TURING's theory of universal computation (TURING machine).

Point 1 specifies a basic dynamic viewpoint. Point 3 acknowledges G. CHAITIN's work on the subject. Point 4 is obviously related to GÖDEL's incompleteness theorem. Point 6 aims at avoiding useless jargon. Point 7 takes RUSSELL and WHITEHEAD's theory of logical types in account. Point 8 is related to homomorphies and isomorphies. Point 9 is of 1st order cybernetics origin and Point 11 takes care of von FOERSTER's 2nd order cybernetics (of "observing systems").

This array of concepts is a kind of abstract generalization of the dynamic toroidal model that Mc NEIL also proposes. Applied to the concept of a General Theory of Systems it gets it out of the purely structural and static trap.

3531

THEORY OF TYPES³⁾

A logical theory that prohibits self-membership in sets (i.e. no class can contain itself as a member), or more generally logical self-reference in meaning systems, in order to avoid paradoxes.

The Theory of Types was elaborated by B. RUSSELL and A.N. WHITEHEAD in their "Principia Mathematica" (1925).

It introduced within the classical dichotomy "true – false" the meaninglessness escape, saving formerly unsolvable logical tangles.

K. KRIPPENDORFF however observes: "... by exorcising self-reference, the theory of logical types has retarded the development of theory, largely cognitive theory, in areas where self-reference is prevalent. With its focus on circularity, cybernetics has transcended the theory and essentially solved the problems self-reference originally posed" (1986, p.75).

This seems right only for the specific viewpoint of second-order cybernetics, as proposed by H.von FOERSTER.

From this angle, R. HOWE and H.von FOERSTER thus state the fundamental point of theory of types: "The properties of the observer shall not enter into the description of his observations" (1975). With this proviso, Epiminedes, who is a Cretan, has no logical right to make any statement on the Cretans that may include himself, as a source of internal contradiction. (as for example, saying that *all* Cretans are liars).

However, from the viewpoint of autopoiesis, no observer finds him/herself in a position to totally separate him/herself of the observed reality, because any external stimulus entering him/her is perceived in accordance with his/her internal organization.

This is not to deny the theory of types, but, on the contrary, shows the absolute necessity to learn to relativize the conclusions that we obtain from our observations of reality.

Theory of types is clearly related to GÖDEL's Incompleteness Theorem, as well as to BATESON's double bind.

→ Logical types (Theory of)

3532

THEORY (Projective)³⁾

Any theory introducing some unverifiable hypothesis – at least provisionally – in order to solve some difficulties, unsolvable within a former theory.

R. VALLÉE points out a trend in contemporary theoretical and mathematical physics to "replace visible complication by invisible simplicity" (in the words of the French physicist Jean PERRIN). This is the case when "to a complicated theory describing perceived reality within the limits of its possibilities, we substitute a simpler theory, but at the same time we introduce a universe partially unknown in its own nature or because of the limitations of our observation means" (1990b, p.41).

Three different cases seem to be possible:

1. The new theory is validated when new and adequate means of observation become available: This was the case with atomic theory in chemistry, with special relativity in physics and astrophysics and with continental drift or plate tectonics in geology.

2. The new theory is falsified in POPPER's sense by some new experiment. This was the case of the ether theory after MICHELSON and MORLEY's experiment.

3. The new theory is neither validated nor falsified, but introduces some unsolvable epistemological enigma.

VALLÉE describes this last type of theories as "projective" as: "So we go (*back*), through a kind of projection (which justifies the name of projective theories given to this type), from an unobservable world, where we have simple laws (we could say a *logos*) to an observable world with complex laws (Ibid). This concept of VALLÉE is closely linked with his "epistemological subjectivity", a unavoidable condition, according to him, of any observing, deciding and acting system.

→ Ontological skepticism

3533

THEORY and PRACTICE

→ Practice (Theory and)

3534

THERMODYNAMICS (First law of)^{2) – 5)}

This law is also known as Law of the Conservation of Energy. In its original form the 1st law stated merely that in an isolated system, the total quantity of energy remained constant, even when transformed from one form into another (for instance, from mechanical to thermal by friction).

Later on, the law was extended to cover the conservation of the mass-energy complex, as for example in nuclear reactions.

The isolation condition is basic, since relationships with other systems or generally the environment would imply exchanges of energy.

Any isolated system has a characteristic energy level: its internal energy, which cannot be properly measured, since this should imply that the system be not anymore isolated: conceptual problems already lurk!

3535

THERMODYNAMICS (Generalized)^{2) – 5)}

In its original limited sense, thermodynamics covers the relationship of heat with other forms of energy (1st Law).

The progressive decay of high energy into equalized heat led to the concept of entropy and to thermodynamics properly (2nd. Law).

Both the 1st and the 2nd Law apply necessarily to systems and become in this way connected with the notions of organization and flows.

The 2nd Law was given a statistical interpretation by L. BOLTZMANN, in which maximum internal entropy corresponds to perfectly scattered and equal distribution of (thermal) energy. But the notion of entropy led to contradictions related to the possibility of systems to fight the downgrading of their internal organization (MAXWELL's demon paradox).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

These contradictions led in turn to a deeper reflexion about the **interrelations** of the system with its **environment** (SZILARD's "exorcism" on **MAXWELL's demon**, 1929) and it became clear that the **isolated system** is a purely abstract and ad hoc concept.

Any **concrete system** as observed by J.H. VOGEL, is to itself a **black box** that **constrains** its **relations** with an **environment** by specifying **inputs** and **outputs** conditions (1988, p.300).

It was now necessary to explain why and how **concrete systems** could maintain their **organization** against the effects of the **2nd Law**. This was the first stage of PRIGOGINE's research, who explained the ways in which an **open system** could remain organized by importing **energy** from its **environment**, stabilize at the lowest, most "economic" possible **level** its production of **entropy** and exporting this **entropy** to its **environment** (Theorem of minimum **entropy production**).

Remained still to understand how systems of a higher degree of internal **organization** could appear in a universe generally dominated by the **2nd Law**. This was the second stage of PRIGOGINE's work, who used the concepts of giant **fluctuations**, **dissipative structuration** and **bifurcations**, all related to the **dissipation** of a **flow** of **energy**, to explain the **emergence** of upgraded **organization**. In R. LEFEVER's words: "In contact with a **source** rich in free **energy**, the system is able to maximize its exchanges with the **environment** and to enter in an **evolutive feedback**" (1979, p.24).

The whole of thermodynamics is thus part of the fundamental bedrock of **systemics**.

3536

THERMODYNAMICS (Limitations to classical) ^{2) - 3) - 5)}

Seen from the systemic viewpoint, classical thermodynamics presents serious limitations, which have been expressed as follows by I. PRIGOGINE: "... classical thermodynamics is an admirable but fragmentary doctrine... This fragmentary character results from the fact that it is applicable only to **states of equilibrium** in **closed systems**. It is necessary therefore to establish a broader theory, comprising **states of non-equilibrium** as well as those of **equilibrium**" (1978).

E. ZERBST notes that: "These states of **equilibrium** are "memoryless" (KATCHALSKY); dead ends of dynamic **processes**" (1972, p.71). This also implies that even a **homeostatic** system, which is open, finally reaches a state (death!), where it has lost any remembrance of its former functionality.

The essential point is that the concept of **closed system** allows for ambiguous and even erroneous interpretations. In general, but more precisely so in thermodynamics, it would indeed be better to speak about "**isolated sys-**

tem", i.e. a system that interacts *in no way* (exchanging no **matter**, **energy** or **information**) with any **environment**. It is only in such a system that the 2nd Principle of classical thermodynamics can be applied without interferences and lead the system to its final **state** of total **random homogeneity**, in which **entropy** has reached its maximum and no free **energy** is anymore available to perform any kind of work. At that **state** one cannot anymore speak of a system, in view that any **concrete system** is characterized by its **heterogeneity**, its **structures** and its functional aptitudes.

L. BRILLOUIN even stated that the 2nd Law is also useless for the study of many purely physical systems, which has since been confirmed by PRIGOGINE and his school's research on a number of physical and chemical reactions.

3537

THERMODYNAMICS (Linear) ²⁾

Linear thermodynamics, established by L. ONSAGER in 1931, apply to **equilibrium** systems, in which the **flows** are proportional to the **forces** in a **linear** way.

From this starting point did PRIGOGINE derive his **minimum entropy production theorem** (in **open systems**).

In such systems, **entropy** production tends to a stable **level** compatible with the degree of **organization** of the system (More organized systems produce more **entropy**, but "export" it to their **environment**).

The theoretical state of **thermodynamic equilibrium** is the final **limit** of **linear** thermodynamics, when **forces** and **flows** vanish.

3538

THERMODYNAMICS (Second Law of) ⁵⁾

"If a physical system is isolated from its **environment**, than the amount of **entropy** in the system can only increase toward a maximum (never decrease)" (A. RAPOPORT, 1966, p.6).

RAPOPORT adds: "Statistically this means that **isolated systems** tend to **drift** from less probable **configurations** to more probable ones, or, which is the same thing, from more "organized" to more "**chaotic**" ones" (Ibid). (Nowadays, RAPOPORT should probably write "disordered" instead of "**chaotic**", since this last term acquired a different meaning.

As stated by RAPOPORT, the system is here simply a portion of the physical **universe**, being well understood that it is **isolated**, i. e. not receiving **inputs** of any kind from — nor emitting any **outputs** toward its **environment**. This is obviously a perfectly theoretical case, of which only a perfectly abstract **model** can be constructed.

If this point is not duly understood, numerous apparent contradictions arise, particularly in relation to **living** and **social systems**, which, of course are **open systems**, able to maintain and even to increase their internal **organization** thanks to organized **matter**, **energy** and **information inputs** from their **environment** and to the possibility to export **entropy** toward that same **environment**.

Even if both situations are a consequence of the 2d Law, there is a clear-cut opposition between the abstract concept of entropic degradation of **order** in **isolated systems** and the more realistic **model** of **self-organization** through a higher production of **entropy** in **open systems**, particularly living ones. H. and L. SABELLI emphasize both aspects and use the greek word "**enantiodromy**" to characterize their complementarity (1994). SABELLI even redefines the 2nd Law as "the **flow** of all **processes** towards **symmetry**, including as such not only the uniformity of **entropy**, but also the creation of complex **attractors** and **structures**".

I. PRIGOGINE considers that "The second law... provides us with a universal law of **macroscopic evolution**, since the quantity of **entropy** appertaining to the system and its **environment** can only increase in the course of time" (1978, p.11) He has however discovered and discussed the thermodynamic conditions applicable to **irreversible systems**, for which the 2nd law remains in check, at least for a **time**.

3539

THERMODYNAMICS (The Second. Law of) as an ATTRACTOR ^{2) - 5)}

This concept has been introduced by R. SWENSON (1989, p 189) in the following terms:

"All real-world macroscopic **change** is **irreversible** and hence governed by **attractors**, viz. the **unstability** of **entropy**-producing **processes**. In particular, the 2nd. law of thermodynamics specifies a maximum **entropy attractor**, S_{max} , the macrostate with the maximum number of accessible microstates, for all macroscopic **change** as $t \rightarrow \infty$. In this sense, all macroscopic **change** is:

1. progressive (goes **irreversibly** towards an **attractor**) and
2. goal-driven (the **attractor** is the **goal**)

"The **attractor** drives the **evolutionary behavior** by virtue of the **instability** of all **states** within the **basin** of the **attractor**, but off the **attractor**".

3540

THERMODYNAMICS (Third Law of) ^{1) - 5)}

"All **processes** slow down as they operate closer to the thermodynamic **equilibrium** making it difficult to reach that **equilibrium** in practice".

K. KRIPPENDORFF, who thus states this law, writes that it is also known as the “**asymptotic law**” (1986, p.76). The concept makes sense, but its relations with thermodynamics in general are not clearly explicated.

3541

THERMODYNAMICS (Equilibrium)²⁾

The final **state** of an **isolated system**, in which no internal **gradient** does anymore exist and any coherent **flow of energy** has disappeared.

I. PRIGOGINE writes: “At thermodynamic equilibrium, complete **disorder** is reached and the probability is maximum” (1984, p. 436).

A curious consequence is that an *isolated* system would be completely devoid of any **structure** or **function** and, therefore not be anymore a system.

P. COVENEY states: “... equilibrium thermodynamics cannot... describe **change**, which is the very means by which we are aware of **time**...”

“It is only by virtue of **irreversible non-equilibrium processes** that a system reaches a **state** of equilibrium. Life itself is a **non-equilibrium process**: ageing is **irreversible**. Equilibrium is reached only at death, when a decayed corpse crumbles into dust” (1990, p.50).

However, “**near equilibrium**” should be carefully distinguished from final static **equilibrium**. A system in **near equilibrium** is still a dynamic one: it is able to maintain its **dynamic stability** or **homeostasis**, by using some steady **energy source** from its **environment**.

Apparent **paradoxes** are due to the purely abstract and unrealistic character of the “**isolated system**” concept, and motivated PRIGOGINE's efforts to develop a more satisfactory **thermodynamics of open systems**, either close to **equilibrium** or far away from it.

3542

THINKING (Integrative) : E. MORIN's seven principle¹⁾³⁾

The french philosopher E. MORIN (1999a, p. 99-101) proposes the following seven principles as guidelines for an integrative way of thinking:

1. The systemic organizative principle, which unifies the **knowledge** of the **parts** with the knowledge of the **whole**.

According to B. PASCAL (1623-1662) it is “impossible to know the parts without knowing the whole or to know the whole without knowing in particular the parts”

2. The **holographic** principle according to which “not only the part is within the whole, but also the whole is “inscribed” in the part”: The holographic principle implies the concept of **emergence**
3. The principle of the retroactive **loop** or **feedback**: the cause affects the **effect**, but the effect may well also affect the cause. This principle leads to the **homeostasis** concept

4. The principle of **recursive loop**, which explains that a system reproduces itself without losing its identity. This is the basic concept of **autopoiesis**
5. The principle of **autonomy** and dependence that states that a system is able to maintain its capacity to sustain itself as a well defined entity only if it obtains the needed **inputs** from its **environment**
6. The dialogical principle (also called **antagonistic**) that states the **complementary** of somehow opposed notions, as for example life and death, or in physics wave and corpuscle
7. The principle of **reconstruction of knowledge**, i.e. the recurrent reconstruction within a cultural **frame** of existing knowledge by the individuals

While this is a quite general overview of **complexity**, other viewpoints are also significant, and in no way contradictory, as for example SABELLI's **priority of the simple** and **supremacy of the complex**, or J. MILLER's **taxonomy of living systems**

→ **Frames of reference; Reconstructability analysis**

3543

THREE BODIES PROBLEM^{3) - 5)}

The problem, first considered by H. POINCARÉ (In “Méthodes nouvelles de la Mécanique Céleste”, 1892-99) is to compute exactly the future or past position at some instant of three celestial bodies whose initial positions and velocities are known and which are submitted to Newtonian reciprocal attraction.

POINCARÉ showed that such a **prediction** was not possible by using anyone of the usual **functions**: **linear**, trigonometric, exponential and their combinations. Moreover he demonstrated that a three bodies system may well be **unstable**.

This has been confirmed during the 1960's by KOLMOGOROV, ARNOL'D and MOSER (The so-called **KAM theorem**), who showed that for some values of the **initial conditions**, the **trajectories** are **quasi periodic**, as if they were integrable, but for other **initial conditions**, arbitrarily close, **instabilities** zones do appear (**chaotic zones**), where dynamics are quite more intricate.

This has been confirmed by computing comets and asteroids orbits, which result **chaotic** in the long run, i.e. subject to significant discontinuous **changes**. Very generally the classical newtonian two-bodies problem is an arbitrary **simplification**, obtained by elimination of secondary **perturbations**. Thus **chaotic dynamics** is also a feature of celestial mechanics and, conversely, it appears that Newtonian mechanics may imply non absolutely **deterministic** consequences.

As explained by R. ROSEN, the three bodies problem has wide implications in relation to the **interactions** of **elements** within any system or for groups of interacting systems: “Yet we might argue that we could study such a three-body system by decomposing it into **subsystems**; a two-body system and a one-body system, both of which are solvable in closed form. This does not help us, because the very act of decomposing the original system in that fashion will irreversibly destroy the dynamical **laws** of the original system; in other words, the properties of the **subsystems** prepared in that fashion will have nothing whatever to do with the properties of the system we are interested in. The properties of the **subsystems** will be *artifacts*. Stated another way, a three-body system is simply not the algebraic sum of a two-body and a one-body system”...

“Now biological systems are typically organized in a manner like that of the three-body system; they resist physical **decomposition** into **subsystems** which would possess the same dynamical properties in isolation that they did when connected into the system” (1974, p. 172).

As expressed by J. CASTI: “The essence of the three bodies problem resides somehow in the **linkages** between all three bodies” (1994, p. 41 – emphasis ours). **Simultaneities** of **causes** and **effects**, when complex, cannot be perfectly modeled, and still less so at **long-term**.

This is possibly the clearest indictment of **reductionism** applied to **complex systems**.

3544

THREE R's of Hard Sciences (The)^{1) - 3)}

P. CHECKLAND characterizes the three basic tenets of hard sciences **methodology** as “**reductionism**, **repeatability** and refutation” He states: “We may *reduce* the **complexity** of the **variety** of the real world in experiments whose results are validated by their **repeatability**, and we may build **knowledge** by the *refutation* of hypotheses” (1976, p.128).

Reductionism allows us to “... systematically investigate a few **variables** in the artificially simple world of the laboratory... to ensure that the results will be intelligible and, hopefully, unequivocal” (Ibid).

On the other hand, “The reductionist is the most enthusiastic wielder of OCKAM's razor... explaining the results using the smallest possible number of concepts” (Ibid, p.131 & 128).

Repeatability, is the basic tool for **validation** in hard sciences.

As to refutation, K. POPPER (quoted by CHECKLAND) stated it as follows: “The **method** of science is the **method** of bold conjectures and ingenious and severe attempts to refute them” (Ibid, p.129).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Unfortunately, none of the three R's can be used freely in the study of **living and social systems**.

Reductionism suppresses most of the significant **interrelations** in living or social **networks**.

Experiences – and still more repeated experiences – are possible on **living and social systems** only in a very limited and generally artificialized way.

And, as a result, refutability is hindered, because it is quite difficult to inscribe specific cases in general hypotheses.

3545

THRESHOLD ¹⁾

The point on a curve of **behavior** where a systems **function** crosses the **limit** of its **dynamic stability regime**.

Below this **limit** the system's **behavior** is not fundamentally affected by excessive **stimulations**. Most generally, the various **functions** within a system are oscillating around a standard value. In such a case "... all **states** are equilibrated when some **parameter function** is less than a certain value, and few or none are equilibrated when it exceeds that value" (W.R. ASHBY, 1960, p.168).

The crossing of a **stability** threshold may either destroy the system, or transform it beyond recognition, within a **process** of **emergence**, and towards a different and frequently more complex **level of organization**.

A slightly different understanding of the threshold is "the minimum-required **stimulation**" to trigger a **change** in the **organization** of a **network** (J.von NEUMANN, 1958, p. 55).

In unstable **composite systems** or **networks**, a threshold defines the minimum **constraint** that must be applied in order to break the **networks structure** and start a global **flow** or an **avalanche** in the **network**, which may also lead to a reordering of its **structure**. Close to such a **constraint** threshold, a very small **disturbance** can start a considerable **change**.

In any case, the crossing of a threshold implies a **discontinuity** and a qualitative **change**. A threshold is a "point of no return" to the original conditions.

3546

THRESHOLD OF STIMULATION ¹⁾²⁾

Thresholds are kind of points of no return. They concretize a **discontinuity** and mostly the shift from a quantitative **accumulation process** to a qualitative **change**.

In many **processes** no such **critical change** appears until resistance to change is overridden by multiple- and sometimes massive- repetition of some stimulation.

It is the equivalent of the common sense saying about "the last straw that broke the camel's back".

Many technical and human **disasters** result from a lack of understanding of this **mechanism** of **discontinuous** change and the insufficient **observation of accumulation phenomena**.

→ **Catastrophe; Power laws**

3547

THRESHOLD UNIT ^{2) - 5)}

"The basic **component** of a **neural network** which produces the **output** 1 if, and only if a weighted sum of all its **inputs** exceeds a given threshold" (P. DENNING, 1992, p.426).

DENNING explains: "The **parameters** of a threshold unit consist of a firing threshold *T* and a set of **inputs** weights *w_i*; these **parameters** are not **binary** but can assume any values on the real number line... In this context **firing** means setting the **output** to 1, and the opposite condition, **inhibiting**, means setting the **output** to zero" (ibid).

The effect thus becomes **digital**.

→ **Parallel Distributed Processing**

3548

THROUGHPUT ²⁾

That part of the **inputs** which is transformed by the system's **activity** into **outputs**.

The specificity of throughputs depends on the nature of the system. Throughput is a quantitative measure of the **efficiency** or **productivity** of the system. However, excessive throughputs, when the internal need for **maintenance** of the system is not covered, may lead to its **collapse**.

3549

TIGHTNESS (Excessive) ^{1) - 2)}

The condition of a system whose **constraints** are reducing **variety** to the point of severely limiting its **adaptive** capacity.

K.DE GREENE writes: "... tightly connected **networks** may be more **unstable** in that the effects of **fluctuations** and **perturbations** in **positive-feedback loops** can spread explosively across the entire **field**".

He adds: "Embodiment of rationalized technological **efficiencies** can destabilize the whole system. For example, computerized **program** trading seems to have increased the severity of the october 1987 international stockmarket crash" (1991 b, p. 72).

As shown by DE GREENE in his paper, **rigidity** and fragility in **complex systems** and **networks**, are closely related to excessive tightness.

3550

TIME ^{1) - 3)}

The concept of persistent existence, duration and succession induced by our **perception** of the sequentiality of **events**.

Trying to define time is one of the most vexing task in any lexicographical endeavor. Any definition always turns out to be somehow circular, as in the given one. We should indeed have to define "persistent", "duration", "succession", "sequentiality" and even "**event**", all of which implies time flow.

The following definition from the American Heritage Dictionary shows the same flaw under a different guise: "A nonspatial continuum in which **events** occur in apparently irreversible succession from the past through the present to the future".

Past and future do not exist "*anywhere*", are only imaginary dimensions of our present **consciousness**, while present is fleeting, cannot be stopped or caught.

E.von GLASERSFELD observes that time dimension is expressed by *verbs*. He states: "This springs from the fact that, when we are analysing a verb, we are dealing with a conceptual **situation** which, under all circumstances, is made up of a **sequence** of **discrete operational** steps: it is, in fact, this very sequentiality that makes the **situation** expressible by means of a verb. That this should be so with verbs designating **activity**, **process** or **change** of any kind, seems obvious: and on closer inspection it becomes clear that it is so also with verbs that designate a **state** – for without there being a **sequence** of at least two **operational** steps which yield the same result (i.e. between which there is no relevant difference that might be registered as "**change**"), we cannot speak of "**state**" (1988, p.7).

Time seems to be part of a complex psychic **frame of reference**. It is not really separable from **matter**, **energy** and **space**. As noted by KORZYBSKI, we cannot imagine some **matter transformation** (nor even permanence), **energy** manifestation or **space frame** outside the time dimension.

As expressed by R.L. ACKOFF and F.E. EMERY, time should be "defined by what it does, not what it is in some metaphysical or physical sense" (1972, p.257). This is in accordance with von GLASERSFELD's views.

The following comment by H. PATTEE illustrates at least partly KORZYBSKI's point: "Time in physics is an irreducible concept, but by no means arbitrary. It is one member of the coherent set of concepts, including **space**, momentum and **energy**, that forms the **language** of physical **laws**" (1978, p.59).

Information does not enter in PATTEE's **set**, obviously because it refers only to the **relation** of the **observer** with the **phenomena**, through material or energetic **markers**.

P. MANZELLI for instance, writes: "... the conceptualization of time is principally derived from **energy/information relationships**, that include the sensible experience of the **observer** into the **description** of the global reality" (1993, p.33).

As **information** is a modulation of some forms of **energy**... in time, and as **energy** itself *flows*, we seem finally enmeshed within a **semantic** vicious circle, which possibly indicates that in our groping for a better **understanding**, we are vainly trying to disrupt a unitary cosmic **frame**.

Irrespective of its "real" meaning – for example in **thermodynamic** terms – time is for us basically a **perception**.

W. PANKOW writes: "**Being is becoming**. Self-transcendent systems are time-generating systems" (1976, p.21).

Within the frame of his extended thermodynamics, I. PRIGOGINE (1973, p.561) has finally put some order in this conceptual and **semantic** morass, as he distinguishes "three levels in the description of time:

- time associated with *motion*
- time associated with *entropy* (**irreversibility**)
- time associated with *dissipative structures*"

About the first level he states: "From NEWTON to MAXWELL and EINSTEIN, time was reduced to a **parameter** in the dynamical **description** of the world: **irreversibility** was only a illusion" (1984, p.61).

PRIGOGINE also makes the following all-embracing observation: "... our physical world has a broken temporal **symmetry**. There exist classes of **initial conditions** which are admissible while their time-inverse is not" (1986, p. 207).

The basic fact about time seems thus to be that it is the most basic "**marker**" of cosmic **asymmetry**. This we perceive through its **irreversibility**, but also its **accumulative historical** significance.

Finally, the nature – and even possibly the existence – of time will remain an enigma until someone discovers some mechanism through which so-called 'objective' or 'real' chronological time could be accurately connected with physiologically and psychologically perceived time.

In any case, time is a basic property and **reference frame** of **complex systems**. Time is somehow equivalent to **causality**: it is its guideline.

3551

TIME (Access)¹⁾

The lapse of time needed to activate some **process**, or elicit some **response** in a system.

Access time is very different, according to the **process** involved. It is related to the speed of the **transmission of commands**.

It can sometimes seriously limit the **efficiency** of the system, but it must anyhow always be taken into account.

→ **Access time for a more specific meaning**.

3552

TIME and ENTROPY¹⁾

Entropy establishes the principle of time **irreversibility**. Moreover, it links downgrading of **energy** and **growth** of statistical **disorder** (BOLTZMANN).

But, what about the reverse **phenomenon** of differentiation and growing **organization**? This subject is thus discussed by J.de ROSNAY: "The time of **observation** is indeed arrowed in the direction of growing entropy: thus in keeping with the arrow of conventional time. But what about the time of creative **action**? It seems to be related to a qualitatively different time, apparently reversed by **consciousness** and aiming towards a direction opposed to a entropy's one: the one of growing **complexity**. How to distinguish this direction from the one of conventional physical time?...

"The 'chronocentric' attitude is quite intransigent. It rejects any consideration about **complementary** between two 'qualities' of time in the way former physicists would accept only **evolution** leading to growing entropy and denied any possible **integration** of biological evolution in their theories.

"Chronocentrism adopts an exclusive logic. Either it accept only causal-type explanations and in this case it relies on the principle of sufficient reason and the **objectivity** postulate. Or, conversely, it accepts only finalist explanations based on a act of faith and a subjective approach.

"The critical difference between these two extreme attitudes is that the causal explanation is strongly privileged in our education and our culture, because it allows for demonstration and scientific proof, while finalized explanation does not permit irrefutable demonstrations, nor scientific proofs" (1990, p.210).

If the polarity between **information** and entropy holds and considering PRIGOGINE and his school's research, there is only one "arrow of time", forthgoing. But it has two different and opposed effects, growing **local organization**, combined by a quickening of the **global** pace of entropization.

Furthermore, the **emergence** of an high level of mentalization in man curiously includes the acquisition of **consciousness** of time and of its **irreversibility**.

And finally, time **consciousness**, while a characteristic of individual **brain-minds**, seems to acquire its total dimension only through social **continuity**, as the individual **consciousness** of time disappears with death.

3553

TIME as an Observer's acquired frame³⁾

K. LORENZ writes: "Almost any higher animal has heredity-bound **structures** in the **organization** of its body and its **behavior** that takes into account such inescapable facts as, for ex-

ample, that no two solid bodies can occupy the same place in **space**; that light moves approximately in a straight line; or that effects always follows cause" (1962, p.41).

It is obviously *sequential* chains of causes and effects that *actualizes* time as a **perception** frame. Such sequences must first be experienced by the young animal in order to activate LORENZ "heredity-bound **structures**" and lead to **consciousness** of time's **flow**.

3554

TIME ASYMMETRY¹⁾

The basics of **thermodynamics** imply the **irreversibility** of time.

This was obscured during a long period because classical physics admitted **reversibility**. Moreover the **MAXWELL demon's** paradox did cast some doubts on the universal validity of the **2nd law of thermodynamics** until it was resolved by L. SZILARD in 1929.

I. PRIGOGINE research has now made definitively clear that the progressive construction of **complexity** implies inevitably time's **irreversibility**.

3555

TIME BINDING^{1) - 3) - 4)}

Ability of a system. to maintain the **memory** of past **situations**, to connect it for use in present action and use it to imagine future possible **situations**, and make plans to try to control these when arising.

The concept was introduced around 1920 by the Polish – American semanticist A. KORZYBSKI (1950a, b).

The time binding capacity grew continuously during the global **evolution**, as the **brain** became more differentiated. With man, endowed with a very complex encephalon this mechanism of preservation of **cognitive maps** acquired an absolutely crucial importance:

- psychologically, because it introduces a permanent **coherence** in **behavior** sequences, *possible only within the time dimension*;
- socially, because it introduces the possibility of institutionalization and **prediction**

Moreover, through technical means (**language**, writing, printing and nowadays all the new media for **transmission** and **storage of information**) time binding is transforming the human species into a global entity, endowed as a **whole** with **memory** and **forecasting** capacity.

More generally, time binding is obviously related to the self-replicative capacity of **complex systems**. **Replication** implies the existence of somehow *stored information*, needed to reproduce **components** and their correct **interrelations** (**organizational closure**).

Biological time, as well as psychological and cultural time seems to depend on the *speed* of the the **replication process**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Time binding capacity also seems to increase with the degree of **complexity** of systems. As shown by V. CSANYI, once the replicative and organizational **process** is launched in human groups, the trend to increasing **complexity** seems an inevitable result (1993, p.268).

3556

TIME DIMENSIONS ¹⁾

The different **period** lengths of different **sub-processes** which take place in a **complex system**.

Their **interconnections** produce a very complicated **trajectory** for the global **process** which may look totally **random**, while in reality it consists of a number of superposed and intertwined **time** curves.

The analysis of these latter is however tricky, since it depends either of the hunches of the analyser or of **Fourier analysis**, which allows for any kind of **decomposition**, significant or spurious.

Most of our evaluations are based on a strictly **linear perception** of the **time-flow** corresponding to some elementary **process** (a watch!), or a complex one artificially thus reduced. Even **nonlinearity** is many times perceived as reducible to lawful regularity. We have scant appreciation of the **long-term accumulations** of effects and the possible **catastrophic** (i.e. **discontinuous**) **changes** they may bring along: "The last straw that broke the camel's back".

We thus need to learn that we may face unsuspected **long-term** consequences of our doings, or that others may experiment them, and in some cases, make us pay for it.

It is possible to speak of "short", "medium", or "**long term**", which appear effectively in many statistical senses related to a great variety of **processes**. However "short", "medium" or "long" may have very different meanings according to the type of **process** which is observed and the considered span of time.

3557

TIME DOMAIN ¹⁾

The duration under which a **process** or a system is active.

Systems have very variable duration. Their **transformations** in time can obey different **rhythms** at different moments of their existence.

In some cases they may extend their time domain in an implicit way for a long span after their apparent disappearance, as conveyed by H. PRAT's concept of **aura**.

3558

TIME FRAME ^{1) - 2)}

The span of time decided upon by an **observer** to study the **dynamics** of a system.

T. BAUMGARTNER et al state: "... in many instances the very **choice** of time frame and research setting will determine whether or not, and to what degree, there is apparent system **closure** and **stability** (or their opposites)" (1976, p.39).

Disregarding this apparently obvious prescription has led to numerous disasters, because in many cases, **closure** and **stability** are assumed over *any* span of time.

The unforeseen (believe it or not!) drying of the Aral Sea is a good example.

3559

TIME HORIZON ^{2) - 5)}

"The last year in the future to which a **model** can be run".

This notion is closely related to J. FORRESTER's **Systems Dynamics**.

According to D. MEADOWS et al: "The time horizon may be an important factor in distinguishing between optimistic and pessimistic futures. Both World 3 and the MESAROVIC/PESTEL **models** reveal problems that may occur some time after the turn of the century. **Models** that have shorter time horizon cannot shed much light on such problems. On the other hand, the more analytically oriented and detailed econometric and **input-output models** are probably more useful for **short-** and **mid-term** projections" (1982, p.103).

In any case, **long term models** are normally more uncertain than **short term** ones, because they include not easily verifiable hypothesis about the future **validity** of **long term trends**, as they *seem* to appear from **data** through the modelizer interpretation. Moreover, let us not forget that **complex systems** may unexpectedly show a **chaotic behavior**.

3560

TIME LAG ^{1) - 2)}

A **delay** in the **transmission** of **effects** between different **components** or **subsystems** in a system.

Time lags are basically caused:

- by **operation lags**, corresponding to the time a **component** or **subsystem** needs to process some specific **input**;
- by transport lags, "which arise from the **delays** occasioned by the moving of materials or other stimuli from the neighborhood of the **components** which produce them to the neighborhood of the **components** to which they serve as **inputs**" (W.R. ASHBY, 1960, p.39).
- It may also represent the duration needed for the exhaust of some systems **buffer reserve** which normally compensates external noxious impacts. A good example is the slow acidification of many lakes, whose effects become obvious many years after the onset of the acidifying influences (W. STIGLIANI &

W. SALOMON, 1993, p.38). This last type of time lag is a very dangerous **phenomenon**, because **long term trends** may remain unperceived for very long time and accumulate potentially massive threats, which may be irreversible when they become clearly visible.

Time lags become of cardinal importance in systems with three or more independent **initial conditions**. As these are generally quite unequal, they reduce, up to a point, the general **coherence** of the system and introduce local **determinisms** disconnecting partly and for the duration of the time lag the **components** or **subsystems** from the rest of the system. This is one of the roots of **chaotic behavior**.

The above described condition is proper to any **distributed system**, be it a human social system, or a **group** of interactive robots or computers. In J.P. VERJUS words, for example: "In a **distributed information system**, there are always **transmission** time-lags, which impede that some **message** emitted from somewhere can be known immediately in other places. As a result, at any moment and any place, it is merely possible to know **approximately** the **state** of other places. It is even possible that... two different **events** taking place within the system could be received in different sequential **order** in various different places" (1988, p.1390).

Time lags, which are inherent in **complex systems**, play havoc with **predictability** and sometimes with **design**. They may seriously disorganize systems, because some **effects** may remain hidden for long time and become irreversible before they are observed. As an example, K. KRIPPENDORFF writes: "In modern society, institutional developments tend to lag behind **changes** in **technology**, causing many social problems... and **conflicts**" (1986, p.42). He could have added "and many **ecological** problems".

3561

TIME LAPSE ^{1) - 2)}

A measured time duration.

Apart from the circularity of defining a time notion using "duration" (or for that "extension"), we also have a problem with **measurement**. Taking due account of the relativity problems with clocks, time measured by clocks is adequate for local physical **phenomena**. But the connection with physiological, psychological, and possibly social time is still quite obscure. See **Time of a system (internal)**.

3562

TIME (Object-in-)

→ **Object-in-time**

3563

TIME of A SYSTEM (Internal)^{1) - 4)}

Biological systems – and possibly social ones – seem to possess a kind of “internal clock”, corresponding however to a non-isochronic flow of **time**, different from one system to another and reflecting “circular logic and **operational closure**” (E. SCHWARZ, 1992, p.770).

Internal time has been researched by P. LECOMTE du NOUY (1936) and A. MISSENARD (1940) in biological terms and more recently by B. MISRA, I. PRIGOGINE and M. COURBAGE (1979) in more general **thermodynamic** terms.

Also R. VALLÉE has developed the very similar concept of “...a time intrinsically adapted to a **dynamical system**”, which he studied in “globally exploding **dynamical linear systems**... in diffusion (or heat) equation (and in)... SCHRÖDINGER equation” (1994, p.33-38).

I. PRIGOGINE et al note: “In addition to the NEWTON-SCHRÖDINGER time, we have to introduce a second “internal:” time describing the **relations** (the “**correlations**”) between the particles” (1991, p.3). And, for large **complex systems**: “... the situation is similar to that of radioactive decay, where lifetime has a meaning only for an ensemble of unstable atoms” (p.5).

The subject remains however still obscure and quite in need of more research.

3564

TIME OF A SYSTEM¹⁾

The specific **time** used by a system of a definite type to perform some **process**.

For example, the reproduction **time** of a bacteria in normal conditions is some hours, while the reproduction **time** of a cow is some months.

3565

TIME PERCEPTION³⁾

This is one of the most elusive issue in general, and in systemics in particular. J.J. GIBSON writes: “We should begin thinking of **events** as the primary realities and of time as an **abstraction** from them – a concept derived mainly from regular repeating **events**, such as the ticking of clocks. **Events** are perceived, but time is not” (1986, p. 100).

L.von BERTALANFFY states that: “Experienced time is not Newtonian. Far from flying uniformly (aequilabiliter fluit, as NEWTON has it), it depends on physiological conditions. The so-called time **memory** of animals and man seems to be determined by a ‘physiological clock’...”

“Experienced time seems to fly if it is filled with impressions, and creeps if we are in a state of tedium...”

“With increasing age, time appears to run faster...”

“Correspondingly, the rate of cicatrization of wounds is decreased proportional to age, the psychological as well as physiological **phenomena** obviously being connected with the slowing down of metabolic **processes** in senescence”

The subject was researched in depth by the French biologists P. LECOMTE du NOUY as early as 1936 and somewhat later by A. MISSENARD (1940) (see above).

It should be added that, just as our **space perception** is defined by our physiological characteristics, our perception of time is also related to it: we have no way to perceive too short **changes**, nor too long ones, while the perception scale of other animals (of very short life for example) could be quite different.

3566

TIME POLYMORPHISM¹⁾³⁾

Time is perceived. As such it is essentially a bio-psychological **phenomenon**. However time **perceptions** are very different, apparently in accordance with what is observed.

R.K. BALANDIN (as quoted by V.V. NALIMOV, 1985, p. 179) notes V.I. VERNADSKY's **observations**, according to whom there are three basic different types of time perception:

- in the radioactive **processes** of decay of atoms we perceive a “time of destruction

“(it should be added that this time is not arithmetical, but **semi-logarithmic**)”

- in many processes, there are **periodic** (and sometimes apparently perrenial) returns to the initial **state**. This is a kind of rotation of time“

- in the evolution of living creatures we register a kind of “creation and **development time**”

Balandin wrote: “VERNADSKY frequently wrote about the unity of **space-time**: each type of space possesses its own time. In other words, each geological object has its own **time scale**.(V.V. NALIMOV, 1985, p.. 45)

Nalimov also quotes H.H. PATTEE who (in C.H. WADDINGTON (ed. 1968) signals the existence of a catalytic time (related to enzyme's activity); a cellular reproduction time; an organism development time; an individual generation time; an ecological succession time and an evolutionary time.

Moreover all these authors seem to overlook EINSTEIN's relativistic concept of time. The meaning of time from the **thermodynamic** viewpoint remains yet also obscure.

The ongoing search for the supposedly fundamental basic unit of time at the micro-, nano-, pico-, etc., **level** adds still another element to this conundrum.

As a (provisional) conclusion, it seems obvious from this quite confusing **panorama**, that there is still something very fundamental missing in our **understanding** of time. It is however clearly a problem of perception and **consciousness** (HUSSERL)

→ **Holomovement; Objectification; Present (the everlasting); Time dimensions; Time lag; Time perception; Time resolution level**

3567

TIME RESOLUTION LEVEL²⁾

G. KLIR explains that, within a selected **time frame** for **observation** of a system, it is necessary to establish:

“1. (A) basic time, which may be represented either by the idealized continous real time measured with respect to an idealized initial time instant, or by a suitable periodic time **event** such as a computer clock

“2. (A) defined time, characterized by a suitable resolution level” (1975, p.151).

“Suitability” is, of course defined in correspondence with significant **changes** of the system to be observed. Climatic and meteorological **changes** must be observed on different time resolution levels. This feature implies problems related to interpolations and extrapolations, which may be more or less acceptable, according to the chosen time resolution level, because this latter acts unavoidably as a kind of **data filter** on the registering of the **state transitions**.

3568

TIME SCALE¹⁾

The normal **span** of duration of a system or a **class** of systems (i.e. a species)

Systems have different **life spans**. This has very important consequences for their perceptive capacity and their specific **activity range**.

For each characteristic natural time **span** (for instance, the second, the hour, the day, the season, the year, the millenium, the geological era) some **phenomena** become visible or invisible.

The perceptive capacity of a **living system**, or a **social system** (and possibly, in the future, of artificial systems) stays in a close relation to its own time **scale**. Humans for example are timed to perceive hourly, daily and yearly **variations**, but the micro-second, the second, the century, the millenium or the geological era escape their normal **range of perception**.

3569

TIME SCALES (Differences in)¹⁾

To cover a similar segment of **transformation** or **evolution**, different systems require different spans of chronological **time**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

BLAUBERG, SADOVSKY and YUDIN express: "This **distinction** may be clearly seen in the following example. In giving a comparative analysis of the **evolution** of two biological species such as, for instance, the drosophile and the rabbit, it would be meaningless to attempt to determine the tempo and character of the corresponding evolutionary **process** in absolute chronological units, for the rate of development of these **processes** are incomparable. The modern biologist therefore employs a unit of **measurement** such as the **time** of replacement of one generation by another and the duration of life of a **population**. In other words, analysis does not involve the concept of **time** in general, but that of the specific time of the system" (1977, p.237).

3570

TIME - SPACE NEXUS ^{2) - 3)}

As noted by I. PRIGOGINE: "The legacy of Newtonian mechanics is a concept of the world in which time is essentially a parameter associated with motion. As early as 1796, LAGRANGE called mechanics a four-dimensional geometry" (1973, p.29).

The introduction of a finite velocity for the propagation of light implied that **space measurement** is possible in terms of timely propagation of light. This **understanding** is now currently used in astronomy (light years). This already dawned in H. MINKOWSKI's mind in 1908: "Space by itself, and time by itself, are doomed to fade away into mere shadows, and only a kind of union of the two will preserve an independent reality" (1923, p.78).

Necessarily, if the velocity of light is finite and if there is no infinite velocity in the universe, propagation of effects in space needs time. This is moreover the condition of the simultaneous existence of separate locations in space. This in turn produces numerous independent **initial conditions** at any moment, the basis for **deterministic chaos**.

D. BOHM and F.D. PEAT state with reference to the space-time of relativity: "Again two apparently incommensurable concepts were discovered to have a deeper unity, and **perception-communication** was extended in physics. Indeed EINSTEIN's was one of the most revolutionary steps taken in the history of science" (1987, p.75).

3571

TIME SPANS for REACTIONS ^{1) - 4)}

"The time available to solve **problems**" (W.D. GROSSMANN & K.E.F. WATT, 1992, p.35).

GROSSMANN and WATT observe that, as specific "amounts of **energy** and material **resources**" are needed to solve **problems** in **human** and **ecological systems**, the time spans available for reactions can be very restricted. This is in fact the notorious "too few, too late"

potential **situation** and implies very great risks in our societies mostly unaware of their own **problems**, or at least of the seriousness of the same, generally because of a partialized non-systemic **perception**.

3572

TIME (Thermodynamic) ^{1) - 3)}

L.von BERTALANFFY writes, (in accordance with PRIGOGINE's **open systems thermodynamics** - as stated in 1947): "The consideration of **irreversible phenomena** leads to the conception of thermodynamic, as opposed to astronomical, time. The first is nonmetrical (i.e. not definable by length measurements), but arithmetical, since it is based upon the **entropy** of chemical reactions and, therefore, on the number of particles involved; it is statistical because based upon the second law; and it is *local* because it results from the **processes** at a certain point of **space**" (1969, p.78).

He also writes: "Thermodynamic time is **non-linear**, but logarithmic since it depends on probabilities; it is for the same reason, statistical; and it is local because determined by the **events** at a certain point. Probably biological time bears an intimate although by no means simple relation to thermodynamic time" (1962, p.75).

These ideas seem consonant with research on biological time carried along by P. LECOMTE DU NOUY and A. MISSENERD in France before 1940. This work was based principally on the differential velocities of wounds healing in relation to age. Biological time seems to be not only local, but also variable in relation to astronomical time.

3573

TIME-CONSTANCY ^{1) - 3)}

The postulate according to which the so-called **laws** of nature have not and will not change through time.

A. RAPOPORT observes: "The metaphysics underlying at least classical physical science is founded on the time constancy of physical **laws**. Mathematically this means that the origin in time of equations of **processes** can be chosen arbitrarily. This in turn, implies that no formulation of a physical **law** is satisfactory if *t*, the **variable** which denotes time, appears explicitly as a **variable** in the equations. Translating into old-fashioned philosophical **language**, this means that time alone cannot be a cause" (1968, p.5).

3574

TIME-ENERGY NEXUS in systems ¹⁾

H.T. ODUM makes the following statement: "The replacement **energy cost** increases as more **organization** and **information** is specified in the assemblage of increasing value" (1971, p.56).

This has been made clear by PRIGOGINE in another way, when he showed that a higher **level** or **organization** in systems implies a higher **level** of **entropy production** (even if the system tends to settle down at the lowest possible minimum **production**).

Moreover, once stabilized the systems tend to evidence a slow increase in **self-reproduction** errors. This has been observed, but seemingly not yet explained.

These different aspects show the intimate relation between energy **flows** and time.

3575

TIME-FRAME MECHANISM ^{1) - 2)}

F. KILE discusses this concept in the following way: "A conscious **element** of a system defines a problem. A second conscious **element** in the same system must define the proper time frame for intelligent **action** in solving the problem. This time frame is defined either by setting a type of **binary** switch which allows the system to proceed only so far without responding to the particular problem definition *or* the time frame is defined by setting an **analog** value which gradually decays (or gradually increases) until the appropriate intelligent **problem-solving action** ensues. If there is not some sort of time-frame mechanism, system **activity** will either stop or degenerate into a sort of **Brownian motion**. i.e. the system would become totally disorganized and collapse" (1975, p.3).

This seems to be special case of J. MILLER's **timer**. Any organized **dynamic system** seems to need some **time control** to coordinate its associated **processes** and foster periodic **control of variables**.

3576

TIMEKEEPER (Biological) ²⁾⁵⁾

A biological **mechanism** that ensures the **stability** of the periodic physiological **rhythms**.

This is a particular case of J. MILLER's **timer**.

The biological timekeeper is situated in the suprachiasmatic nucleus, a **brain structure**. It controls for example the **circadian rhythms**.

J. TAKAHASHI and colleagues identified a specific gene situated on chromosome 5 as the biological timekeeper and found it to be active in the suprachiasmatic nucleus.

(Ph. COHEN, 1997, p.16)

3577

TIMER ²⁾

"The **subsystem** which transmits to the **decider information** about time-related **states** of the **environment** or of **components** of the system".

This is one of J.G. MILLER's **20 critical subsystems** in his **taxonomy of living systems**. It was however introduced only in 1990, i.e. 25 years after the original work, in an ar-

ticle by Jessie MILLER (1990), who states: "Living systems, at all **levels**... have an **information-processing** system, the timer. The timer consists of one or more **oscillators** known as clocks or pacemakers, the **phase** of which can be reset. They measure duration or **order** in **time** or underlie **rhythms** of various sorts. The timer **subsystem** synchronizes internal **processes** of the system and coordinates the system with its **environment**" (p.164).

It is very significant that, in parallel with PRIGOGINE's generalized **thermodynamics**, SABELLI's **process theory**, and with **chaos theory**, the MILLERS now also acknowledge the unavoidable need to introduce **time** in our understanding of **complexity**.

The timer can be studied through the system's **life cycle**, its **periodic** variations, and be useful for **forecasting** and **planning**.

3578

TIME's ARROW ¹⁾

The expression was created by A.S. EDDINGTON (1929).

However, in the laws of classical physics and quantum mechanics, it is impossible to distinguish between past and future. (See "**Reversibility and entropy**").

Nevertheless, daily experience shows us that new entities appear "at any moment", only to decay "later on" and that we cannot do without implicit or explicit references to that enigmatic **perception** that we call "time".

In P. COVENEY's words: "...as the physicist Ludwig BOLTZMANN discovered, it is not possible to base the arrow of time directly on equations that ignore it. His failed attempt to reconcile microscopic mechanics with the **second law of thermodynamics** gave rise to the "**irreversibility paradox**" (1990, p.51).

The "legalization" of time's arrow in physics required more than 100 years, in three steps:

1) The introduction by R. CLAUSIUS in 1850 of the concept of **entropy** as a quantity that relentlessly increases in relation to progressive **dissipation** of heat and levelling of internal **energy states** in an **isolated system**.

The formulation of the 2nd Law as an **inequality** implies in fact giving a privileged direction to time.

2) However, as no real systems are absolutely isolated and as they can maintain successfully their internal **organization** through absorption of **energy** from their **environment**, a more realistic approach was necessary. This was done by I. PRIGOGINE with his theorem of **minimum entropy production** in **systems near their equilibrium** (1945) (1947) However, this theorem still explains **stability**, more than irreversible **transformations** and/or decay

3) One more (and decisive) step was taken by P. GLANSDORFF and I. PRIGOGINE (1971). They

showed that **systems far-from-equilibrium** could jump from one **stable state** to one of some alternate others, through a **bifurcation** brought about by **dissipation** of **energy** through giant **fluctuations** that could not anymore be damped.

From another viewpoint, as noted by M. HAAS "Time is perhaps the most ineluctable foe of **symmetry**" (1967, p.71).

It could also be said that time's arrow is the basic vector of **causality**, which could never become manifest in "no time".

In a somewhat more precise perspective, P. MANZELLI states: "The **irreversibility** of natural **phenomena**, i.e. the reality of the arrow of time, can be described... as a fundamental consequence of the evolutive asymmetrical character of the **dynamics** of **matter/information/energy transformations** in nature" (1993, p.234).

As experimental proofs became numerous, it can be admitted that the "arrow of time" is now firmly established in a scientific perspective. What remains now to be found out is how and why *we perceive* time physiologically and psychologically.

3579

TIMING ^{1) - 2)}

The external and/or internal **synchronization** of one or various systems or **subsystems**.

Timing is referred to the **interactions** of **simultaneous** or **sequential processes**. Such **interactions** cannot be completely **random** if the system is to maintain an internal **coherence** and **survival** capability in its **environment**. Timing is an **order parameter** and J. and J.G. MILLER's **timers** are timing devices.

3580

TINKERING ¹⁾²⁾⁴⁾

The **process** of upbuilding of more **complex systems** by introducing some new features in already existing **forms**

This concept has been proposed in his 1982 book by the french biologist F. JACOB as a fundamental process in biological **evolution**.

Tinkering is of course done through "**trial and error**". In **living systems**, "trials" are mutations, and "**errors**" are those **mutations** which are directly lethal or introduce negative factors which finally lead a species into a dead end.

Tinkering seems also to play an important role in the **evolution** of man-made **objects** and techniques in general.

It would be interesting to study the possible role of tinkering in social innovation and evolution.

3581

TIPPING POINT ¹⁾²⁾

The **threshold** at which the **rhythm** of **growth propagation** of some **phenomenon** ceases to be **linear** and becomes exponential (P. MARS-DEN, 2000, p.46).

The concept has been introduced by epidemiologists. It has however a much more general significance for many **phenomena** of similar behavioral characteristics. It should be compared with **avalanches**, **self organized critical systems** and **percolation models**.

It has been proposed also in relation to the **propagation** of **memes** as "mental **epidemics**" (M. GLADWELL, 2000)

3582

TIT-for-TAT STRATEGY ²⁾⁴⁾

In a **game**, a **strategy** that repeats the opponent's previous **behavior**.

This **strategy** can lead either to mutual defection, or to **cooperation**. Some quite unsuspected and interesting alternatives can emerge if some specific **complementary rules** are introduced, as for example, the existence of a longer "historic **memory**" in the players. (C. EMMECHE, 1994, p.92-99)

Such **rules** can better explain **phenomena** of **co-evolution** in different **populations**, or positive **reciprocity** in societies.

3583

TOKEN ^{1) - 3)}

Something that serves as a **representation** of some registered experience.

H.von FOERSTER thus explained his use of this term: "**Objects** and **events** are **representations** of **relations** determined by modes of internal computations: hence "**objects**" appear to reside exclusively (sic) in the **subject's** own experience of his sensory/motor **coordination**. The externality of communal **space** is established within the social **context** of other **subjects**; also **recursively** experiencing "**objects**" as tokens of sensory/motor **closure**. Thus tokens for stable **behavior** are "tokens for **Eigen-functions**" (1981, p.274).

In this extremist view, **objects** (or "**objects**"?) are merely a kind of illusive intersubjective currency. This is acceptable only if one maintains a cautious **ontological** agnosticism, but should not lead to a radical negation of "outside there" reality, which would carry us back to pure **solipsism**.

This must be part of what a French humorist called "les dangers de l'auto" (i.e. of auto-poiesis).

R. GLANVILLE saves the point as he writes about the common view of "**objects**" in se "with their own description built in" that "this meaning is very different from the notion of

"object" as "built through the mutually complementary roles of **observer** and **observed**" (in G. KLIR (Ed.): "Applied General Systems Research, 1978)

In another paper GLANVILLE also stated that a non-observed object "inhabits the **universe** unknown to others" (1978)

3584

TOLERANCE^{1) - 2)}

"The relative capacity of an **organism** to endure an unfavorable **environment** factor or **change**" (UNE, 1983, p.27).

This definition from the UNESCO - UNEP "Glossary of environmental education terms" can be extended to any type of systems. Tolerance is specific to each type of **inputs** for each type of systems. It can vary according to the **state** of the system. It may for instance increase if the system acquires some type of resistance or **immunity**. And it may decrease when it undergoes internal disabling **processes**. Different systems have distinctive tolerance **limits**, for different **inputs**. The tolerance **limits** of different individuals of the same **class** or species generally vary somewhat. This is for instance, how and why resistance tend to develop globally, but slowly, in species, against chemical or drug fighting means.

3585

TOOLKIT PRINCIPLE²⁾

Any new emergent type at a higher **level** of **complexity** in an evolutive **process** is the result of the **integration** of **elements** pre-existing at a lesser **level** of **complexity**.

It avails in fact to a tentative explicative **macro-mechanism** for a generalized concept of **evolution**. This concept has been introduced by W. SCHWEMMLER (1991, p.153, p. 163).

It is in fact a systemic generalization of L. MARGULIS concept of **symbiosis** in cell **evolution** (1981). The concept is also more or less implicit in C. BRESCH work on stages in **evolution** (1977) and in V. CSANYI's **zero-system model** based on **sets of components** which this author calls "**autogenetic system precursors**" (1993).

It could be very useful in the study of the world ecological and social **globalization process** presently in progress.

3586

TOOLS (Conceptual)³⁾

A **set** of concepts that can be used for the study of some **classes** of **situations**.

M. LIU describes as follows the general characteristics of **systemic** and **cybernetic** conceptual tools:

"(1) Global approach tools characterize **interactions**, not **objects**. (They refers for example to: **logics**, **values**, attitudes which specify **relations** between entities).

"2) Such concepts do not describe intrinsic properties of reality,... but indicates some path to characterize some concrete reality.

"3) The conceptual tools emphasize what is general and what is specific. This means that they are not destined to discover only **structures**, which would be **invariant** in whatever **situations**, but are also useful to discover altogether the specific traits of every **situation**.

"4) They are non-disciplinary and apt to characterize the results of very numerous **interactions** related to different aspects" (1989, p.43).

In synthesis, the **systemic-cybernetic** conceptual tools allow us to find new **knowledge algorithms** related to complex **wholes**.

3587

TOP DOWN^{1) - 2)}

The organizational **mode** of a **machine** made of **subsystems** performing **subfunctions** and ordered in such a way as to contribute to the accomplishment of the predefined global **function** of the **machine**.

A good example is the building of a plane, for which a very detailed blueprint has been previously established, describing in great detail the interconnected **functions** of the multiple **parts**, as well as the **parts** themselves.

Such a system is a strongly **integrated** unit. So it is because it has been imagined and constructed in a preconceived way by its creator. It is quite well adapted to the finality assigned to it, but is unable to adapt itself to different **situations**, outside of the **limits** of his predefined finality.

In classical A.I., the top-down approach implies the need for **algorithmic rules**, which, by nature are not adapted to not foreseeable **situations**.

The "top-down" organizational mode is complementary but also antinomic to the "**bottom-up**" one, which is better adapted to social type **situations**. (See more explanations under the heading "**Intelligence (Distributed Artificial)**").

The "top-down" models fit centralized **control** of **interactions**, but tend to ignore the real **complexity** of systems. The "bottom up" **models** tend to become over-complicated, very difficult to integrate in a coherent way and to apply to real **situations**.

Bottom-up construction and top-down **management**, in natural systems, **regulation** or **control** are in a **dialectical** relation.

Any **process** of emergent **complexity** implies recurrent **interactions**, that must be multi-correlated and stabilized.

If taken in a properly dynamic and sequential sense, H. SABELLI's Principle about "**Priority of the simple, supremacy of the complex**" resumes very well the unavoidable **complexity** of the two processes.

3588

TOPOLOGICAL DYNAMICS²⁾

Name given to **chaos theory** by the American School of St. SMALE in Berkeley and the Soviet School of A. KOLMOGOROV, Y. SINAI and V.I. ARNOL'D in Moscow (1989, p.42).

I. STEWART comments: "The very jargon of **chaos** has strong geometrical flavour: **phase space**, orbits, **flows**, **mappings**, **sources**, **sinks**, **saddles**, **attractors**, **bifurcations**, **tangles**, **period-doubling cascades**" (Ibid).

More could be added: **basins**, **separators**, **limits**, **thresholds**, **Poincaré sections**, **trajectory**.

Much of it derives from POINCARÉ's **analysis situs**, the original name of **topology**.

3589

TOPOLOGICAL SPACE²⁾

"A mathematical **structure** on which **continuous processes** can be defined" (R. ROSEN, 1979, p.179).

ROSEN states: "One of the basic problems of topology is to determine whether two such spaces are indistinguishable from one another from the standpoint of the **continuous processes** which may be defined on them: if this is the case, the two spaces are said to be **homeomorphic**" (Ibid).

3590

TOPOLOGY^{1) - 2)}

The branch of mathematics concerned with the study of the properties of the geometric **configurations** which remain **invariant** under **transformation** by continuous **mapping**.

Topology studies properties like nearness (i.e. **neighborhood relations**), deformations through local or global expansion or contraction, equivalence of **forms** from a geometrical viewpoints, etc...

Basically, as stated by R. ROSEN, topology studies the notion of **continuity** (1979, p.179).

That which remains **invariant** in such cases is the proximity **relation** between points, in such a way that there are neither ruptures or fusions as a result of the **transformations**. Thus distortions like pulling, bending, stretching (but not tearing) do not affect the topological properties of figures.

This type of **transformations** is called **homeomorphisms**.

Topology studies qualitative properties related to the relative positions of geometric species, independently of their form or dimensions.

Topology was originally called by H. POINCARÉ "Analysis Situs", or situational geometry and developed by him.

In Bertalanffy's words it is a study of relational mathematics including nonmetrical **fields** such as **networks** and **graphs** theory.

Topology is useful for constructing general **models** of **structures** and their continuous **transformations**.

It is suggestive that some biologists, around 1928-1935, as WOODGER, NEEDHAM and WADDINGTON, sensed the possibility and the need (in BERTALANFFY's words) of a non-quantitative **mathematics**, or "configuration mathematics" which would give priority to concepts of form and order.

It can be used to study basic nonnumerical **relations** between the **elements** of organized systems and the relative **stability** or **unstability** of their **structures**.

Topology concerns itself with **concepts** like: **attractors**, **basin**, **enveloppe**, **partition**, **trajectory**, **vicinity**, etc.... (C. BRUTER, 1974).

Catastrophes, **fractals**, **graphs**, and **groups**, are related mathematical concepts.

3591

TOPOTAXIS¹⁾ - 2) - 4)

The tendency of free **elements** of the same kind to form **clusters** in some limited **region** of the available **space**.

Topotaxis seems to result generally of a growing excess of **population density** in a constrained area.

A classical example is the clustering of **Dictyostelium discoideum** when food becomes insufficient for the increasing **population**. Another is the gregarization of solitary locusts, in similar conditions.

Topotaxis seems however to be a typical systemic concept, as a spontaneous **process** leading to socialization and the genesis of more **complex systems**. The notion could be useful for the study of some **agglutination phenomena** in human societies, as for ex. the formation of megalopolises.

3592

TOROID²⁾

A possible general **representation** of 3-dimensional **phenomena** produced by **field dynamics** (Adapted from D. Mc NEIL).

Helical **dynamics** are the result of **interactions** between **fields**, as in **vortexes**. In abstract, a torus should be a specific **topological attractor** for this kind of movements. However, in many **complex systems**, the imbricated character of their internal **organization** needs be represented by more complex forms, including toroids containing toroids.

Mc NEIL generalizes the **topological torus**, using fully its dynamic character, that results from the complementary opposition of two types of displacements.

And: "... toroidal contours represent dynamic, connected **volutions** rather than the separate, rigid **structures** or the hermetically encapsulated nuggets found in so many conventional **worldviews**" (1993 a, p.15).

Or: "Toroids map the conceptual space into comprehensible orders without resorting to artificial **linear dichotomies** or rigid arrays of pigeon holes" (1993 b, p.14).

Mc NEIL states: "Natural as well as artificial toroids can be generated in many ways other than by the rotation of a plane figure... Toroidal forms can be traced by continuous spirals of **helical dynamics**" (1993 b, p.9).

As to the toroidal dynamics: "In the **context** of a simple toroidal **whole**, the center is the **region** closest to **equilibrium** in the sense that the **meridial** as well as the annular **fluxes** are most concentrated there, much as a whirlpool captures and holds what would otherwise drift along in a stream. The periphery of the toroid is farthest from **equilibrium**, with relatively diffuse currents and cross-currents over relatively broad surfaces" (1993 b, p.16).

Mc NEIL offers the tree, as a general graphical and **dynamic representation** of a toroid. This is at the same time a good **homomorphic model** of real trees and a **metaphorical model** of any system which obtains **inputs** from an **environment**, **metabolizes** them and produces **outputs**. This tree **model** is widely different from the classical tree **model** of **hierarchical organizations**, or a **computer program**: It is not merely the representation of a **structure**, but altogether one of the ongoing **process** or **processes**.

Any **living system** seems to be basically a toroid, and this **model** also fits stellar systems, hurricanes and possibly **ecosystems** and **social systems**.

It should be taken into account that toroids become easily **unstable**.

The now rediscovered **toroidal model** seems to have been first introduced by C.L. WEYHER as early as 1887! (as quoted by C. LAVILLE, 1950, p.54).

→ **Vortex**

3593

TORUS²⁾

"The three dimensional figure described by the rotation of a closed two-dimensional figure across an axis offset from its center" (D. Mc NEIL, 1993 b, p.9).

Mc NEIL comments: "The torus has many consequential **topological** features which a simple sphere or spheroid does not. For the purpose of a systemological definition however, one of the most important of these is the way in which the torus represents a break in the three-dimensional **symmetry** of the sphere. The torus is thus an oriented figure which can **channel**, **direct**, **select** and **control** along its axis, e.g. a duct, a conduit, or a pipe" (1993 b, p.9).

In some sense, the torus differentiates an "inside" from the "outside", and becomes an

abstract **model** for the most various kinds of systems.

For more about the torus, see R.H. ABRAHAM and C.D. SHAW (1988, p.558-73).

3594

TOTAL SYSTEM INTERVENTION (TSI)⁴⁾

"A total **systems approach** to planning, designing, **problem resolving** and **evaluation**" (M.C. JACKSON, 1993, p.1004).

According to R.L. FLOOD and M.C. JACKSON, TSI consists of three phases **creativity**, **choice** and **implementation**. Seven principles are embedded in TSI:

- **organisations** are too complicated to understand using one **management "model"** and their problems too complex to tackle with the "quick fix";
 - **organisations**, their **strategies** and the difficulties they face should be investigated using a range of systems **metaphors**;
 - systems **metaphors**, which seem appropriate for highlighting organisational **strategies** and **problems**, can be linked to appropriate systems **methodologies** to guide intervention;
 - different systems **metaphors** and **methodologies** can be used in a complementary way to address different aspects of **organisations** and the difficulties they confront;
 - it is possible to appreciate the strengths and weaknesses of different systems **methodologies** and to relate each to organisational and business concerns;
 - TSI sets out a systemic **cycle of inquiry** with **iteration** back and forth between the three phases;
 - facilitators, clients and others are engaged at all stages of the TSI **process**" (1991b, p.50).
- The authors give the following examples of systems metaphors to be used, "some of which concentrate on organisational **structure**, (while) others highlight human and political aspects of an **organisation**":

- The **organisation** as a "**machine**" (**Closed system view**)
- The **organisation** as an "**organism**" (**Open system view**)
- The **organisation** as a "**brain**" (**learning system view**)
- The **organisation** as a "**culture**" (emphasis on **norms** and **values**)
- The **organisation** as a "**team**" (unitary political system)
- The **organisation** as a "**coalition**" (pluralist political system)
- The **organisation** as a "**prison**" (coercitive political system)"

They add: "The main aspects of **organisations** highlighted, and those neglected, by each **metaphor** will be disclosed in order to enhance discussion and debate. The outcome (what is

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

expected to emerge) from the **creativity** phase is a "dominant" **metaphor** which highlights the main interests and concerns and can become the basis for a **choice** of an appropriate intervention **methodology**... If all the metaphors reveal serious problems then the **organisation** is obviously in a crisis state" (p.51).

M.C. JACKSON explains the methodology as follows:

"During its **creativity** phase, TSI uses all the systems perspectives or **metaphors** introduced (above) (mechanical, **organismic**, **brain**, cultural, political) to encourage creative thinking about **organisations** and their problems. Some **metaphors** concentrate on revealing problems with organisational **structure**, while others highlight human and political aspects of an **organisation**. What is expected to emerge from the **creativity** phase is an enhanced appreciation of the key issues facing the **organisation** at the time of the analysis...

"The task during the **choice** phase is to choose an appropriate systems-based intervention **methodology** (or **set of methodologies**) to tackle the key issues facing the **organisation** as revealed by the examination conducted in the **creativity** phase. What is required, clearly, is a good understanding of the strengths and weaknesses of the various **methodologies** available and knowledge of what **issues** each is most useful in tackling... The most probable outcome of the **choice** phase is that there will be a dominant **methodology** chosen, to be tempered in use by the imperatives highlighted by dependent **methodologies**. **Choice** of a **systems approach** (or approaches) in this way ensures that it addresses the main concerns of the particular **organisation** and should yield highly relevant and co-ordinated intervention.

"The intervention then progresses to the implementation phase. The specific **methodology**, or **methodologies**, chosen are used according to the special logic prescribed by TSI, in which the positions of 'dominant' and 'dependent' **methodologies** can shift as the intervention proceeds. The outcome of the implementation stage is coordinated **change** brought about in those aspects of the **organisation** currently most vital for its effective and efficient functioning.

"It is important to stress that TSI is a **systemic** and **iterative approach**. It asks, during each phase, that continual reference be made back and forth, to the likely conclusions of other phases" (ibid).

FLOOD and JACKSON themselves offer a critical **evaluation** of TSI, as a theory, as a methodology and as an ideology (?), as well as of its practical utility (1991b, p.241-5).

TSI offers obvious similarities with J. WARFIELD's **Generic Design** and with I.I. MITROFF and H.A. LINSTONE's **Unbounded System Thinking**.

3595

TOTIPOTENCY¹⁾

Ability of some undifferentiated **elements** to generate a new complete system or **subsystem**.

The first demonstration of this strange systemic property was DE VRIES' experiment of dividing an urchin embryo and obtain two perfectly constituted urchins from the separated **parts**. The same **process** is now currently applied in botany in order to obtain from meristemes a number of genetically identical plants.

The regeneration of some animal **parts** when severed (for instance in lizards) seems to show that, in some cases, some cells of mature **living systems** may return to totipotencial undifferentiation (Demonstrated in 1997 through the successful cloning of the ewe "Dolly" in Edinburgh).

A different, but also regenerating **process** is the spontaneous local reconstruction of a partly disabled **network**, as for instance in a **brain** after a not too severe cerebral haemorrhage.

It would be interesting to investigate the relation – if any – of totipotency with **holographic processes**.

3596

TOTIPOTENTIALITY¹⁾

The ability of a **living system** to perform all the **critical subsystems processes** needed for life.

This concept has been introduced by J.G. MILLER (1978, p.18). MILLER makes however a subtle distinction: Only mature systems are totipotencial; in their **growth** period, their **reproducer** is not yet operative.

MILLER (ibid, p.302 for instance) seems however sometimes to use the concept with the **meaning** of **totipotency** (see above).

3597

TRADE-OFF²⁾

"An exchange of one aspect for another and the consideration of the effects of such exchange" (P. VENDRYES, p. 90).

Trade-offs are an interesting aspect of **complex systems behavior**: their wide **variety**, in ASHBY's terms, or **stores of reserves**, in VENDRYES' ones, allow for **choice** among many possible **behaviors** and better potential **accomodation**.

3598

TRADE-OFF DECISION⁴⁾

"A compromise or exchange which **decision** makers must effect when all their **objectives** cannot be carried out at the same time" (J.van GIGCH, 1978, p.119).

The **goal** of trade-offs is **optimization**. However van GIGCH observes that there are false trade-offs, "those that promote "sector improvements" solely within one system or at one system **level**, while neglecting the trade-offs among different systems and systems **levels** and while overlooking the **objectives** of the total system. These false trade-offs are called **suboptimization**" (p.133).

Good trade-offs thus depend on a correct **understanding** of the **interrelations** between **levels** in systems or their **relations** with their **environmental meta-system**.

3599

TRAINING^{1) – 3)}

The **process** of constructing, by **iterative** exercise, any basically automated physical or physiological **behavior**, or mental **algorithms** and **frames of reference**.

Training does not however suppress completely any latitude in **behavior**: it merely tend to define in each case a specific **range** of acceptable **activities**.

Any training is based on **reinforcement** by repetitions. **Learning** is more of a specific training of neuronal connections in the **brain**, mainly in the neocortex.

It seems to be basically a **process** of establishing behavioral or neural **constraints** in order to define in a precise way the potential activities of a system.

→ **Constructivism**, **Habit**, **Hebb's rule**, **Learning**, **Organizational Closure**

3600

TRAINING (Methods of Systemic)^{1) – 2) – 3)}

A set of practical methods to train young people in order to transmit them the **perception** and understanding of **complexity** and, when possible and suitable, the ability to **control** it without harmful side-effects.

The ability to understand complex **situations** by progressive **adaptation** and **accomodation** is natural in human beings. All of our early training as newborns, infants and young children is of systemic and cybernetic nature. Rational **understanding** and analysis intervene only later on. Unfortunately these belated mental acquisitions tend to obliterate the global **perception** and **understanding** or, at least, to impede its use for the study more global **situations**.

In order to maintain it some young Argentine systemists proposed, and experimented with the following **methods** used in:

"**Systemic workshops**: Creating a **transdisciplinary** area of work, using a global approach to real problems as they appear in the everyday life of the young students. This can be done

starting from very general and open thematic cores as for example "youth", "our **environment**", "our neighbourhood", "the **communication media**", etc...

These subjects are developed through debates, excursions, games, videoscreening, audio-visual material, readings, interviews, etc...

"Trade workshops: Training in some specially selected trades as for example integral bakery, paper recycling, vegetable gardening, through which systemic **processes** are presented without any need to use very abstract concepts. Such a work facilitates the **understanding** of three main systems: the person, the society, and the **environment**, in their most general sense. It is an optimal way to develop a better **understanding** of oneself and of natural, physical, mental and social **processes**."

"Workshop with teachers and authorities: Generating a broader thematic and methodological approach by stimulating a more integrated view of reality and a better **understanding** of the global **interrelations** between teachers, pupils, families and the socio-cultural **environment**. In this case, systemic and cybernetic concepts and **models**, applied to real **situations** can be quite useful, if used within the workshops, mostly in an applied non tutorial way."

The experiments met with quite successful results, but no significant support could be found for their extension.

(B. ANGRIMAN, L. FLORIT and A. QUIROGA, pers comm., 1993).

3601

TRAJECTORY ²⁾

A sequence of values of a **variable**, indexed with **time**.

3602

TRAJECTORY in classical representation ²⁾

F. HEYLIGHEN states that, in classical **representation** mode, trajectories are closed "...in the sense that the system must follow a given trajectory: It cannot leave it and follow another trajectory or it cannot enter it from another trajectory, since the **reversibility** and **predictability** of classical **evolution** precludes any branching of trajectories. Mathematically, the trajectory may be called **linearly** closed (i.e., there is a complete, **linear** order **relation** between the points of the trajectory)" (1990a, p.435).

3603

TRAJECTORY of a network ²⁾

The succession of **states** of the network (1991, p.66).

Such a trajectory is usually very complex in networks including numerous **elements**, even when some of these are integrated in stable **subsets** (KAUFFMAN's "**Frozen cores**"). As all the **elements** act simultaneously, the **behavior** of the networks tends to be **deterministically chaotic**, i.e. not really **random** but apparently so. It does become at times practically unpredictable.

3604

TRAJECTORY (Stability of a) ²⁾

J.L. CHABERT and A.D. DALMEDICO write: "The concept of stability may take different meanings. The oldest one, adopted by LAGRANGE, corresponded to the strict **periodicity** of a trajectory. POISSON broadened the notion to the case in which the trajectory comes back not necessarily to its starting point, but an infinity of times in the close **neighborhood** to this starting point" (1992, p.296).

At the end of 19th century, POINCARÉ demonstrated that some trajectories are not stable, i.e. that after diverging from their starting point, they remain forever far from it. He thus introduced the seeds of **chaos theory**.

3605

TRANSCODING ²⁾

"Transfer of **information** from one **code** to another".

Generally, when some **information** enters into a system, it is quickly transcoded. For example, part of the electromagnetic waves are perceived as light by means of a complex conversion through our visual **subsystem**. This **process** may be indirect, for example when the electromagnetic waves are first converted into images through a television tube.

Thus, "**information** must not be confused with its support" (I. BLAUBERG et al., 1977, p.119).

3606

TRANSCULTURATION ⁴⁾

The crossing-over from one culture into another by an individual or a group of individuals.

Cultures are well-defined **human systems**, each more or less, or very different from any other one. A culture "imprints" individuals and make them fit to live within the **human system** they were born in... which may mean unfit to integrate themselves within another one.

Transculturation is a very difficult and frequently a quite traumatic **process**, because the transculturing individual must accept **values**, **norms**, and generally behavioral ways that are different and in many cases contradictory to those she/he learned in her/his mother culture.

A **pathology** of transculturation could be established in systemic terms. It could explain for example fundamentalism and extreme nationalism. It would also probably be very useful in order to avoid so-called "racial" **conflicts**, which seem to be basically cultural ones.

3607

TRANSDISCIPLINARITY ^{1) - 3)}

The general characteristic of **cybernetic** and systemic concepts, **methods** and **models** which provide specialists with a **metalanguage** for the study in common of **complex situations** in systems.

R. RODRIGUEZ DELGADO writes: "Transdisciplinarity is a global **perception** of the ultimate **connection** of all or many disciplines. From this perspective, not only science but all human activities appear as an unitary **whole**, **part** and parcel of the unity of universe. Unity and **diversity** do not appear as opposite concepts, but as complementary perspectives" (Pers. com., 1990).

Transdisciplinarity, as a systemic notion, is quite different from **interdisciplinarity**, or **multidisciplinarity**.

P. CHECKLAND writes: "The call for "**interdisciplinary** teams" to tackle social problems is a popular one, but 30 years' experience in **Management Science** has emphasized that this is not a successful way to tackle such **problems**, rather the fact that it is quite remarkably difficult for specialists from one discipline to understand the concepts and **language** of another.

"What we need is not **interdisciplinary** teams, but transdisciplinary concepts, concepts which serves to unify **knowledge** by being applicable in areas which cut across the trenches which mark traditional academic boundaries" (1976, p.127)

Ch. FRANÇOIS writes: "Transdisciplinarity implies:

"1. The existence of a **metalevel** of **models** and concepts, leading to an integrated **understanding** by every part-taker of the system under study;

"2. The existence of a common **metalanguage**, based on **isomorphies** useful to convey generalized concepts and **metamodels**" (1986, p.115).

The creation, for instance, of a **meta-model** of the possibility to **control** or **regulate complex systems** of any kind (i.e. by **feedback**) may lead the specialists:

- to better understand systems studied by other specialized disciplines
- to collaborate usefully and smoothly in global projects
- in some cases to gain new insights in his/her own discipline and gain much time by avoiding the need to rediscover from scratch concepts or **models** already in existence.

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

The creation of such a crosswise "**meta-tools**" box is possibly one of the most important goal of systemics and cybernetics.

Accordingly, Russell A. ACKOFF states: "Effective research is not disciplinary, **interdisciplinary** or **multidisciplinary**, it is **transdisciplinary**" (1999, p.426)

And: "The **whole** can be understood only by viewing it from all the perspectives simultaneously". And moreover: "Science, I believe, consists of the search for **similarities** among things that are apparently different; the humanities consist of the search for differences among things that are apparently similar. Science and the humanities are the head and tail of **reality**, viewable separately, but not separable" (Ibid, p.427)

FRANÇOIS adds however a caveat: "Let us be very clear and unambiguous: these general concepts or **models** are *identical representations* obtained from *different* specific **situations**, **interrelations** or **processes**. Each discipline studies its own problems in its own terms. However, there generally exist some common traits underlying apparently dissimilar settings or **situations**" (Ibid., p.118-9).

Transdisciplinarity should by no means be taken as a possible substitute for specific disciplines.

K.D. BAILEY, in a recent paper (2001, p. 41-62) explored the multiple traps in the construction of what he calls "concept exportation" across disciplinary **boundaries**. Curiously, while his goal is progress "towards unifying science", he does not use the term "transdisciplinarity", which seems to fulfill exactly his intention and **understanding**.

3608

TRANSDUCER^{1) - 2)}

Some device or system that conveys **matter**, **energy** or **information** from a system, or **sub-system** to another one or, from or to the **environment**.

J. MILLER defines three types of transducers: **input**, internal and **output** transducers, all related to **information** processing. For **matter-energy** transport he uses three other labels, namely: **ingestor**, **converter** and **extruder**, which obviously correspond to the three **information** transducers.

Some authors, as for example T. ÖREN use the concept of "**energy transducer**" in the following way:

"An **energy** transducer is a device that either:

- 1) converts an **input energy** into an **output energy** that is of a different nature than the **input energy** or
- 2) provides **knowledge** about the **input energy**.

An **active transducer** directly generates an **output signal**. A **passive transducer** requires additional excitation **energy**, which is modified by the transducer" (1990, p.12).

ÖREN distinguishes the three following types of transducers:

"The first type of transducer is an **energy-converting** device that can sense **energy** (heat, radiation, or sound) and convert it into electrical, pneumatic, hydraulic, or another form of **output signal**. Examples include microphones, thermocouples and piezoelectric transducers...

"The second type of transducer: 1) receives stimulation from a physical **situation** or condition that is the object of **measurement** (the measurand) and 2) converts that stimulation into a definitely associated **signal** that is more appropriate or convenient as **input** to a **measurement** system.

"A computer **program** is a **knowledge** transducer. Similar to any energy transducer, a computer **program** has an **input knowledge** and an **output knowledge**" (ÖREN, 1990, p.13).

MILLER's **input**, internal, and **output** transducers are other example of ÖREN's third type, but not only in man made **mechanisms**, since they exist at the eight **complexity levels** described by MILLER from the **cell** to the supranational system with various kinds of **energy** and **information inputs** and **outputs**.

Moreover, it seems that the word "**knowledge**", as used by ÖREN in the present context, could be replaced by the word "**information**" (see B. ZEIGLER comments on "**knowledge**" and *internal representation*, 1986).

3609

TRANSDUCTION²⁾

Any **transformation** or **coding process** that modifies an **input** or **output**.

Transduction is generally necessary in order to harmonize the **interrelations** between a system and its **environment**, or between **subsystems** within a system.

3610

TRANSFER FUNCTION

The emission of an **output signal** by a **neurode** after computation of the total of incoming **inputs** from other **neurodes**.

→ **Brain; Parallel Distributed Processing; Stigmergy**

3611

TRANSFER (Inverse)^{2) - 3)}

An implicit **operation** by which an observing and acting system attributes "some of its intrinsic traits... to the part of reality it succeeds in apprehending" (R. VALLÉE, 1990b, p.40).

VALLÉE who introduced the concept, stresses the deformations that the systems **observation process** as well as the **decision** one transmit to the objective **situations**.

He writes: "The theme of "inverse transfer" of intrinsic traits of the observing (and even deciding) system, somehow generalised, gives some elements of answer to the classical interrogation of the intelligibility of the world. If the world is considered sometimes intelligible, not without effort indeed ("Der Herr Gott is nicht bese aber raffiniert" wrote EINSTEIN), it may be partly due to the fact that *our ways of perception, understood in the widest sense, eliminate all that does not fit our mind*. Then through "inverse transfer" some of our intrinsic traits are attributed to the part of reality which we succeed in apprehending" (p.40).

As an example, our classical mathematics could modelize some *chosen* physical properties. However, to explain some others (for example the **3-bodies problem** when it was recognized as a problem in its own right), new mathematics were needed and introduced, starting with POINCARÉ. Later on, important extensions of these mathematics could be used as a new tool to try to understand **deterministic chaos** in general.

It would be interesting to study specific cases of inverse transfer that may probably be observed:

- in superior animals, whose **observation**, **decision** and **pragmatic operators** are at variance with ours
- through cultural differences, in relation to MARUYAMA's **mindscapes**
- during the **evolution** of a same culture through time, for example in relation to the **paradigmatic mutations** described by Th. KUHN (1970).
- in psychologists, who adhere to different theories
- in individuals adepts of different **ideologies**.

3612

TRANSFORM³⁾

In mental **processes**, the **effects** of a **coded** version of some registered **difference**. (Adapted from G. BATESON, 1979, p.109-14)

Any perceived **difference** (i.e any **distinction** made) is not merely registered by the **brain**, but becomes "translated" according to a **code** proper to the **observer**. The code may be differential and even **hierarchical** and produce various "translations".

BATESON comments, referring to KORZYBSKI's **metaphor** about "the map is not the territory": "KORZYBSKI's **map** is a convenient **metaphor** and has helped a great many people, but boiled down to its ultimate simplicity, his generalization asserts that the **effect** is not the **cause**" (p.110).

Of course, but KORZYBSKI carefully mapped the so-called **effects** (plural!), as related to different **frames of reference**, in his **structural differential**.

3613

TRANSFORMATION²⁾ – 4)

1. "A **set of transitions**, on a **set of operands**" (W.R. ASHBY, 1958, p.10).

This is the most abstract formulation of this concept in cybernetic terms. The "**set of transitions**" supposes the existence of a **code**, that can be represented as a **transformation table** (p.11), a **transition matrix**, a causal **network**, or a **graph**.

The observed transformation can be for example: one to one; one to many; many to one; or some more elaborately defined one. The basic idea is to define the way of pairing in general. For details see ASHBY (Ibid).

Another important feature of transformations is that they can operate as a closed (i.e. **cyclical**), or an open set.

→ hereafter: "**Transformation (Principle of non-proportional)**"; "**Translation rule**".

2. "The **process** by which an **input** is changed into an **output**." (B. BANATHY, 1973, p.90).

BANATHY elaborates in the following way:

"**Transformation control and adjustment** are **operations** whereby transformation is monitored. The **information** gathered through monitoring is analyzed and interpreted in order to introduce **adjustments** by which to improve transformation.

"**Transformation facilitation** is a **set of operations** aimed at the continuous energizing and **maintenance** of all **components** that participate in transformation" (Ibid.). (A good example is **catalysis**, in its most generalized sense).

"**Transformation processing** refers to such **operations** as transformation, production, systemization, facilitation and **control**.

"**Transformation production** is a **set of operations** in which the **subject** (i.e. the **component** or **part** we are interested in, or observing) of the system and other system **components** are engaged, interact, and use **resources** in order to accomplish the purposed transformation (of the **subject**...) and thus achieve the **goal** of the system" (1973, p.90).

This last paragraph is redacted in a somewhat partialized way because BANATHY refers himself specifically to the student as the **subject**, i.e. learning **component** in an educational or **training system**.

By **subject**, BANATHY also more generally means "... the entity around which the system is organised and which has to be transformed by the system..." (Ibid). Examples of such a subject could be a school, or a club or any other organization to be transformed by all its participants.

"**Transformation model** is a conceptual **representation of operations** by which the **input** is changed into **output**." (Ibid.)

3. Within a system, the **operation** or **process** by which an **input** is changed into an **output**.

In J. MILLER's **taxonomy of living systems**, this **process** is shared among the following **subsystems**:

a) **processing of matter or energy**: **Distributor, Converter, Producer**;

b) **processing of information**: **Internal transducer, Channel and net, Decoder, Associator, Encoder**. (1992, p.4).

TRANSFORMATION (Baker)²⁾: See "**BAKER's transformation**".

3614

TRANSFORMATION (General Theory of)

Rafael RODRIGUEZ DELGADO in his last work advocates the constitution of a "General Theory of Transformation" (1997, p.27).

Such a theory should coordinate **autogenesis** and **self-organization** (V. CSANYI's "**zero-system**", for ex.); **self-reproduction** (i.e.: MATURANA's "**autopoiesis**"); **growth**; **dynamic stability** and **fluctuations**; **cycles** and **functions**; **catastrophes** in the THOM and ZEEMAN sense; **chaotic processes**; **emergence**; **disintegration**; **synergetics** (HAKEN); **self organized criticality**, and possibly other aspects.

The role of **timers** should be also taken in account and the whole subject framed in classical and Prigoginian **thermodynamics**.

3615

TRANSFORMATION MODEL²⁾ – 4)

"A conceptual **representation of operations** by which the **input** is changed into **output**" (B. BANATHY, 1973, p.90).

BANATHY's definition applies mainly to **planned** transformations in human systems. However, models of transformation in natural systems can also be constructed and be useful to better understand **change** in such systems. Of course, in every case, the model is based on **observations** and hypotheses that should be frequently revalidated.

3616

TRANSFORMATION (Principle of non-proportional)^{1) – 2)}

"As any **structure** grows, the proportions of its **parts** and of its significant **variables** cannot remain constant" (K. BOULDING, 1956, p.71).

BOULDING explains this principle in the following way: "It is impossible... to reproduce all the characteristics of a **structure** in a **scale model** of different size. This is because a uniform increase in the **linear dimensions** of a **structure** will increase all its areas as the square, and its volumes as the cube, of the increase in the **linear dimension**. Thus a twofold increase in all the lengths of a **structure** in-

creases its areas by four times and its volumes by eight times. As some of the essential **functions** and **variables** of **structure** depend on its **linear dimensions**, some on its areal dimensions, and some on its volumetric dimensions, it is impossible to keep the same proportions between all the significant **variables** and **functions** as the **structure** grows" (Ibid).

d'Arcy Wentworth THOMPSON in his fascinating work "On Growth and Form", first published in 1916, scrutinizes a considerable number of consequences of this principle, mainly in biology and engineering. His concept of transformation is basically geometrical: New biological **forms**, for example, are obtained by the deformations of a geometrical grid. But it is clear that the transformation **model** can be adapted and extended to animal and human social **organizations** and explain generally numerous problems linked with gigantism. BOULDING gives some striking examples.

3617

TRANSFORMATIONS (Topological)²⁾

d'Arcy Wentworth THOMPSON observed (1916) that numerous **forms** – principally in biology – while apparently very different, could be related to each other by continuous deformation (**Homotopy**).

N. RASHEVSKY noted that "Topological **analogs** go much deeper in the realm of the living when we observe not merely structural but functional (in a biological sense) **relations**" (1956, p.125).

In support of this, he showed the possibility of the construction of global **graphs** of the biological **functions**, as, for example **assimilation**. This is an interesting generalization of the concept of topological transformation, certainly applicable to very different kinds of systems, as for example human **organizations**.

3618

TRANSFORMITY¹⁾

"The **energy** by unit **energy**"

Being **energy** the total **energy** used to produce the **emergence** of some **field** condition or system, S. ULGIATI et al., state that transformity "has **thermodynamic** significance indicating the position of an item or **process** in the **energy hierarchy** of the universe" (1992, p.1121).

For example "Solar transformity (is) the solar equivalent **energy** directly and *indirectly* required for a joule of product" (Ibid).

In many cases the *indirect* requirements of **energy** in some production **process** are forgotten. This leads to over-optimistic **evaluations** of production in terms of **energy** use, as shown for example by D. PIMENTEL (1977).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3619

TRANSIENT STATE ^{1) - 2)}

"A system state which cannot anymore be occupied again when that system reaches one of its **equilibrium states**" (After K. KRIPPENDORFF, 1986, p.77).

KRIPPENDORFF states that transient states occur during the **growth** of a system, or during **evolutive processes**, and even in social and technological **development**. He adds the very important observation that "**Behavior** involving transient states is also **non-ergodic**" (Ibid).

The contemporary growing general economical, social and political mayhem very probably is a succession of transient states for humanity evolving towards its planetary **integration**. Transient states seem also related to **dissipative processes** in **systems far-from-equilibrium**.

3620

TRANSITION ¹⁾

The **process** of passing from one **state** to another.

W.R. ASHBY states that a transition "is represented by a pair of **states**, one at time *t* and one at the specified time later" (1960, p.248).

A series of transitions generally corresponds to the **trajectory** of some **variable**.

3621

TRANSITION (BÉNARD's) ²⁾

"The crossing from a molecular **chaos** dominated **regime** ... to a much more complex one where part of the **energy** is transferred into macroscopic fluid currents" (adapted from R. LEFEVER, 1979, p.13).

In BÉNARD's experiment – heating a jar of water – this **phenomenon** starts with convection currents within the jar, replacing the simple thermic agitation. When the liquid nears the boiling point, the accelerating convection currents lead to the appearance of **hexagonal structures**: BÉNARD's **dissipative structures**. This **phenomenon** seemed merely a curiosity until PRIGOGINE did generalize it as excess **energy dissipation** through giant **fluctuations** in **systems far-from-equilibrium**. Without such an **energy flow**, "the possibilities of formation of **dissipative structures** are absolutely negligible" (Ibid, p.15).

It is now well established that BÉNARD's transition is a very general **phenomenon**, even in biological and **social systems**, as shown for example by P.M. ALLEN's and colleagues work on **urban systems** (for instance 1984, p.230-248).

→ **Instability (BÉNARD's)**

3622

TRANSITION (Discontinuous) ²⁾

The sudden **emergence** of a new **steady state** after a **bifurcation** in a **system far-from-equilibrium**.

Such transitions appear beyond a **threshold** at a critical distance from **equilibrium** and result from self-amplifying **fluctuations** which cannot anymore be damped and controlled by the system.

These non-equilibrium transitions lead to qualitatively, i.e. evolutive new **states**.

3623

TRANSITION (Principle of asymmetric) ²⁾

"The probability of transition from a less stable **configuration** A to a more stable one B is larger than the probability for the inverse transition" (F. HEYLIGHEN, 1992a, p.5).

HEYLIGHEN comments: "The conjunction of **energy** conservation and asymmetric transitions implies that **configurations** will tend to dissipate **energy** (or heat) in order to move to a more stable **state**" (Ibid).

This is why systems of higher **complexity**, while producing more **entropy** than systems of lower **levels of complexity**, will settle to the least possible **level of entropy** production compatible with their **level of complexity**.

This however does not impede the **process** of **dissipative structuration** in systems submitted to excessive **inputs of energy** in relation to their **level of complexity**. In such cases, **instability** sets in until a new sustainable **level of complexity** is attained. Thereafter, the principle of asymmetric transition is reinstated.

A different way to asymmetric transition described by E. PESSA (1992, p.437) is the "disappearance of **chaotic behavior** and the **emergence** of ordered ones (e.g. **limit cycles**)" through the "mechanism of **noise-induced transitions**". This seems to be closely related to the **nucleation mechanism** described by PRIGOGINE.

→ **Order from noise principle**

3624

TRANSITION PROBABILITY ²⁾

The probability of a shift from one **state** to any other possible one between **elements** which are at least in partly **random interaction** in a system.

This type of **sequential changes** is characteristic of **Markovian** systems and can be represented by a **matrix**.

It can be observed in ASHBY's **homeostat**, and is subjacent in **artificial life automata**.

→ **Markovian System**

3625

TRANSITION PROBABILITY MATRIX ²⁾

A matrix which represents all the possible transitions from one **state** to any other in a **Markovian system**.

G. PASK describes it as follows: "P is an *n.n* matrix with *n*² entries *p_{ij}* and $\sum p_{ij}=1$ rows and columns corresponding with the **states** *J(i)* in a column vector. Each row in the matrix represents the probability distribution obtained by selecting the **state** in correspondence with this row, as we do in multiplication with the column vector *J(i)*. The **state** of a **Markovian system** can be represented as a point in a **probability space** with *n* co-ordinates *p₁, p₂... p_n* one to each **state**. This **space** should not be confused with the **phase space** with *m* co-ordinates related to the **attributes**" (1961a, p.122).

3626

TRANSITION (Rule obeying) ²⁾

A **situation** in which each of the various possible transitions between the different **elements** of a system is constant.

Let us say for example that the **probability** of a transition of the element B to C will always be 0,13 while the transition from element A to D will always be 0,21, in a system where the total of possible transitions between elements is 1. The general basic **model** has been developed by ASHBY (1956). In most natural systems and **artificial life** systems the **probabilities** may vary, being submitted to weight **adjustments** in a **process of parallel distributed processing** (D. RUMELHART & J. MCCLELLAND, 1986)

Rule-obeying processes have been also considered by J. BRYANT (1998), who views the **brain** as a rule-obeying system (p.113-120)

→ **Markovian matrix- Markovian process**

3627

TRANSITION STEP ²⁾

"An **instability** region between two **stable equilibria**" (V. ROWLAND, 1976, p.123).

The **region** thus defined by ROWLAND corresponds to a **discontinuity**, also considered by R. THOM in his **catastrophe theory**.

3628

TRANSITIONS (Register of the) ²⁾

The record of the successive **states** of a system.

Such a record becomes richer with **time** and allows in a progressive way a better **knowledge** of the system's **space of states**.

This **knowledge**, however remains always imperfect for very **complex systems**.

3629

TRANSITIVITY ²⁾

"**Relation** of two **parts** through a middle **part**" (after J. FEIBLEMAN & J. FRIEND, 1969, p.32).

A typical transitive relation is: If $A < B$ and $B < C$, then $A < C$. On the contrary, if $A < B$ and $B > C$, nothing precise can be said about the relation of A to C .

FEIBLEMAN and FRIEND give the following example: "... The **parts** of an apple are transitive, for if the skin ...encloses the flesh, and the flesh encloses the seeds, then the skin encloses the seeds". Conversely "An **aggregation** of three grains of sand is **intransitive**, since the extreme **parts** are not related to each other by a middle **part**" (Ibid).

It is possibly not *that* simple. In **composite systems**, we find a kind of global statistical transitivity. The **set** of the grains of sand, or the **set** of gregarious locusts has an influence on the individuals, whose **behavior** become oriented. And the **set** is obviously composed of these same individuals who acquired some collective properties, due to their **aggregation**.

This is one of these cases where an abstract definition of a concept must be carefully scrutinized, in order to avoid semantic pitfalls.

3630

TRANSLATION^{1) - 3)}

"The act of changing the **signs** in a **message** from one **language** to another" (R.L. ACKOFF & F.L. EMERY, 1972, p.190).

ACKOFF and EMERY state: "Thus translation presupposes **encoding**. The **sender**, **receiver** or intermediary may translate a **message**" (Ibid).

The main problem with translation is the faithful reproduction of **meaning**, because **meanings** are **implicit** in every **language** (which are systems of interconnected and somewhat **fuzzy meanings**) and with specific shades in each case. This is one reason why computer translation is such a difficult job.

3631

TRANSLATION RULE²⁾

"A **bijective function** by which each **element** of the support **set** is assigned another (unique) **element** of the same support **set**" (G. KLIR, 1991, p.53, p.221).

→ **Bijective relation; Transformation**

3632

TRANSLOCATION²⁾⁵⁾

The displacement of an **element** in an ordered **set**.

A **change of location** of a part or element within the **whole** to which it belongs.

The properties of the whole can be quite seriously affected by such a change.

Translocation sometimes occurs in arrays of DNA. An example in micro-biology is the displacement of a gene within a chromosome.

However, this **phenomenon** seems general in character and leads to the reorganization of the system. In many cases its general **organization** and functional **activity** is more or less deeply modified.

3633

TRANSMISSION LAG^{1) - 2)}

"The delay occasioned by the moving of material or other **stimuli** from the **neighborhood** of the **components** which produce them to the **neighborhood** of the **components** to which they serve as **inputs**" (R. ROSEN, 1960, p.39)

The transmission lag is a **time lag**, different from the **operation lag**, also defined by R. ROSEN.

The transmission lags contribute to limit the **coherence** of the system and to render it **heterogeneous** in **space** and **time**. They difficult **coordination** and **control** and may become a desintegrating factor in extreme cases. But they also introduce a measure of leeway for **components** and **subsystems**, which may well be necessary for a better (and even global) **adaptability**.

3634

TRANSMITTER¹⁾

Any device or system which emits **messages** and send them to potential **receivers** through some appropriate **channel**.

The transmitter must code the **messages** in a double way. First, some **energy** must be modulated according to some rules and made apt to be conveyed by the **channel**. This is basically SHANNON's **communication**.

Moreover, the message should "make sense", i.e. have a "meaning", which must moreover have the potential to exert some **trigger effect** on the **behavior** of the **receiver**. In order to achieve this, a second **code** is necessary to establish a system of meanings.

DNA, RNA and neurons are transmitters, possibly in a somewhat **metaphoric** sense. So are radio and TV stations and those people who operate them, i.e. who use electromagnetic **codes** to transmit **semantically** coded **messages**.

3635

TRANSPARENCY^{1) - 3)}

Referred to by J. WARFIELD as "referential transparency": "Referential transparency is required from **methodology** back to theory, and from theory back to foundations. Moreover it is required from applications forward and throughout all three of these components of a science.

"Ultimately, referential transparency is a **description** of a **relationship** between an interpreter and what is to be interpreted..."

"Working against referential transparency is the following formidable collection of difficulties:

- What constitutes a science is implicit;
- Divisions of many **component** concepts are implicit;
- The **universal priors** of science may be treated as implicit, in the presentation of the science;
- definition of concepts by **relationships** may be implicit in the science;
- The underlying basis of arguments in the theory of **sets** may be implicit;
- The underlying basis of arguments in the theory of **relations** may be implicit;
- The foundations of the science are implicit;
- In some instances, especially in newer areas of technology, even the theory is implicit.

In the ultimately reprehensible **situation**, even the **methodology** may be implicit" (1988, p.340).

In brief, the **invisibility** of the implicit can lead to considerable opacity of any **representation** and make its value highly doubtful. This is also a caveat for systemists!

Moreover, transparency also implies a "sometimes implicit aspect of **communication** - (i.e.) interpretive **symmetry** between originator and **receiver** of **communications**, summarized in four essentials:

- "a. That the linguistic terms needed to represent either exist in the **language** or will be created as required;
 - b. that a way to organize the **description** exist or will be created;
 - c. that the **design** of the **representation** will employ the foregoing;
 - d. that the **representation** can be assimilated by both the originator and **receiver**.
- "All these essentials depend on the awareness of basic **language** types" (Ibid).

Some of the reasons why **systemics** is so resisted in some quarters are closely related to WARFIELD's views. There is a wide gap between generalist and specialist **languages**, and this gap should be eliminated by the systemists if they ever want to be listen to.

→ **Frame (mental); Reference frame**

3636

TRANSPARENCY TO ONESELF³⁾⁴⁾⁵⁾

The lack of **perception** of one's own cultural, social and historical conditioning in mental **beliefs** and psychical **processes** as well as behavioral **attitudes**. In fact, the result could be better called "opacity" to whatever else!

J. ORTEGA Y GASSET, in his study of DILTHEY's work (1965, p. 143) writes that man is more alert of his surroundings and much less so of himself. Paradoxically, being transparent or even invisible to himself becomes a very significant **blindspot** in the management of his **relationships** with his material, mental and social **environment**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This seems to be a fundamental problem specially affecting close-minded and intolerant people. When affecting many people, it can lead to **social pathologies**.

→ **Autogenesis; Autopoiesis; Hermeneutics**

3637

TRANSPUTER⁵⁾

A **component** endowed with some capacity of processing, characterized by four receiving and four emitting **connections**, which enable it to communicate easily with four other transputers.

When interconnected, four transputers constitute a kind of super-transputer with eight possible receiving and emitting external **connections**. This **process** can go on in order to create very complex integrated **networks** with various **levels** of **nested** transputers.

Such **components** are the basic "bricks" of any massively **parallel** integrated systems.

The transputer has some functional similarity with the formal neuron.

3638

TREE²⁾

A branching **graph** used to represent a **hierarchy**.

See: **Graph theory**

3639

TREND^{1) - 3)}

A more or less general regularity in a **process**.

Different trends appear according to **time horizon**. Some are related to **short**, other to median, **long** or very long **term** (in a relative sense). These different **time scales** are interconnected and the **observer** must define the **process level** in which he/she is specifically interested, in view that any trend is normally related to a specific aspect of the **process**. The simple statistic analysis of **data** proposed by **operation research** and called trend analysis, while technically useful, is insufficient and even risky as a **forecasting** tool, if **short term** trends are not distinguished as **fluctuations** in the **longer term** trends (at various **time horizons** at that!).

In systems in **dynamic equilibrium**, the **longer term** trend generally constitutes a limiting **frame** for the **oscillations** of the shorter ones. When the **short term** trend line nears the **limit** (superior or inferior) of the longer one, a reversal of the short one generally takes place and a **short term threshold** is crossed. For this reason, any extrapolation of a shorter term trend is risky and doubtful, if nothing is known about the longer ones.

Of course, the **time scales** of trends **observations** are conventional as they depend on the type of **processes** which are observed.

While one day is a long span in a mayfly's life, one year amounts to practically nothing at geological **scale**. However, even in this case, a sudden discontinuity may happen at any time, as a **chaotic event**: an earthquake produced by the slow **evolution** of a geological fault.

Short term trends may appear as being **random** if related to **long term** ones. However, they may well depend from some micro-**determinism** whose visible expression may even be statistical. In this sense, M. BELIS states: "During the **progress** of some **phenomenon**, the necessity, as dominant trend, opens its way through the multiplicity of fortuitous **events**" (1987, p.59).

While no prediction can ever be absolutely guaranteed, the **observation** of **long term** trends combined with shorter ones is the most reliable tool at our disposal.

3640

TRENDS (Types of)^{1) - 2)}

In the study of system's processes, it becomes very important to distinguish clearly between different types of trends:

- Linear or nonlinear
- asymptotic
- exponential, or logarithmic
- logistic
- cyclical

It is also of significance that some section of a curve, observed within a too short time bracket, may lead to erroneous interpretations concerning the trend as a whole.

3641

TRIAD²⁾

1. A group of three **elements**, normally of the same kind
2. Two interacting systems that produce a third one at a higher **level of complexity**.

Only this second definition is of real interest, because it describes the most elemental building block of any kind of systems. This **process** was described by C.S. PEIRCE as "thirdness".

3642

TRIADIC RELATION²⁾

The **semiotic relation** between **object** and interpretant through **sign** or **symbol**.

The triadic relation was the great discovery of C.S. PEIRCE, according to whom "....but one triadic **node-type**, with two in-branches and one out-branch is necessary for infinite **variety of structure**" (Quoted by H.M. PAYNTER, 1968, p.76).

Many contemporary developments as for example **general semantics** (KORZYBSKI), **learning matrixes** (STEINBUCH), **constructivism** (von GLASERSFELD), **generic design** (WAR-

FIELD), **process theory** (SABELLI) have been, directly or not, influenced by the triadic model.

The basic triadic act is **naming**, i.e. creating a **symbolic** bridge between **subject** and **object**. Obviously, it is the **subject** who **constructs** the bridge. The ignorance of the naming act and its relative value, induces **ontologic** absolutism with its aftermath of logical, psychological, conceptual and practical problems. As a result, J. WARFIELD insists in his lectures that "Questions are superior to assertive hypotheses as bases for scientific study" and that "Every question involves **contextual** implications" and if and when a point can be reached "where there is no contextual implication (we reach) the axiomatic domain" (pers. comm.).

Of course, within the axiomatic domain, we cannot speak about anything concrete: we have reached mental **organizational closure**. No systemist should ever forget this when constructing a **model**.

F. FRISCHKNECHT and J.van GIGCH have used an "Information-System-Processing triad" as the "Common core of human disciplines" (1989, p.239-252).

3643

TRIADICITY^{2) - 3)}

The union of opposites to form a new **element**.

This concept, used by J. WARFIELD and H. SABELLI, originates in C.S. PEIRCE's "thirdness", implying a (**semiotic**) mediating third **element**, the **symbol**, in-between **object** and **subject**. This is very different from HEGEL's synthesis. PEIRCE's idea is thus expressed: "The logical postulate for explanation forbids the assumption of any absolute. That is, it calls for the introduction of thirdness" (in J. HOOPES, 1991, p.187).

Escaping from limited **duality** and resulting dichotomies, triadicty is a very simple combinatory **algorithm**, basic for any systemic construction, as it introduces the notion of multiple **relationship**, supplementary to merely dyadic **linear** ones.

E. SCHWARZ explicits triadicty as follows: "Any existing system, a bacteria for example, has two plus one aspects: Its anatomical physical **structure**..., the abstract non visible **network** of **causal relations** between its **parts** and **processes**, which is responsible for its functioning, and the **cell** itself as a complex **whole**, as a **totality** without which the **parts** would not work, would have no meaning. We believe that these three aspects: physical **structures** and **fluxes** in **space** and **time**; logical organizational **networks** of abstract **relations**; and existent **totalities**, have different **ontological** status, and correspond to deep universal **categories**..." (1994, p.758).

This leads to an "interactive, non-a (i.e. **non-aristotelician** in Korzybski's vocabulary) ternary, conjunctive logic, in which the **interaction** between two terms generates a third and new **holistic** term including, integrating, and of another nature than the two parents and the relation" (p.771).

3644

TRIAL and ERROR¹⁾

An empirical **method** tending to solve some problem or establish some theory through repeated experiments, reducing progressively the **uncertainty**.

Trial and errors **methods** are costly. One of the uses of **systemics**, as proposed by L.von BERTALANFFY, is to guide this type of research, using **metaphors**, **analogies** and, if possible **homomorphies** or, better still **isomorphies** with problems already solved in other disciplines. General **models**, as for example **regulation by feedback**, **dynamic stability**, **dissipative structuration**, etc... may give an insight to the experimenter, aiding her/him in looking for some specific features. Of course such possible short-cuts should be used prudently.

3645

TRIFURCATION^{2) - 3)}

The creation of a third dimension by co-creative **interaction** of the opposites.

This concept has been introduced by L. CARLSON-SABELLI and H. SABELLI, principally in psychotherapeutics.

They state: "Seeking the trifurcation of opposites serves to understand **patterns** that are otherwise obscured by the tendency to think in pairs of opposites" (1994, p.681).

Trifurcation is the dynamic correspondent of **triadicity**.

→ **Dichotomy**

3646

TRIGGER¹⁾

Some **stimulus** or **disturbance** which produces a chain of **responses** in a system.

Different from a simple **stimulus**, the trigger starts a whole **process**, which may propagate itself far from the first **receiver** and during a long **time**, including effects whose relation with the first impact is far from obvious.

The trigger **process** is sometimes at first apparently insignificant. While it may not be clearly perceived, nor understood when it happens, it has sometimes the potential to wholly transform or even destroy a system.

In **risk analysis** or **assessment**, a good study of as many as possible typical trigger incidents leads to a better earlier **forecasting** potentiality of possible **disasters** (or in cases, positive developments) in the making.

3647

TRIGGER EFFECT^{1) - 2)}

An initially small variation in a **process**, which may initiate an **amplifying mutual causal process**.

A trigger effect may, in some cases, "give rise to rapid and unexpected **changes**" (F. ROBB, 1989, p.54).

It corresponds to the sudden **dissipation** of a quantity of potential **energy**, many times in a quite explosive way. Of course, a potential for **instability** must exist, if **regulation by negative feedbacks** and **homeostasis** are to be overcome.

Being the case, the onset of growing and eventually, giant **fluctuations** may lead to the eventual destruction or **transformation** of the system.

Trigger effects come in very different **scales** in **time** and **space**. The most insidious are the ones resulting from a long and slow **accumulation** of some **stress** in the system, as for example the sudden rupture of equilibrium in a seismic fault, or arterial embolism resulting from a blood clot.

At the planetary system level, man's **brain** may be the most important source of trigger effects, due to its very high rate of **energy** processing.

→ **Criticality, Nucleation**

3648

TRIGGERING QUESTIONS²⁾

Those questions that are innovative and trigger new viewpoints or an **inquiry** into some formerly unsuspected issue. The paradigmatic example is SOCRATES' maieutics

→ **Brainstorming; Interpretive structural modeling**

3649

TRIVIALIZATION¹⁾

The **transformation** of the **behavior** of a system from more or less unpredictable to predictable.

The **concept** has been introduced by H.von FOERSTER.

He observes that **complex system** are generally speaking **non-trivial**, in that the same **input** does not necessarily produces the same **output**.

He notes that we mostly try to construct **trivial machines**, i.e. **machines** whose **behavior** will respond to our expectations because we built them along **deterministic rules**. We also try trivialize our **environment**: "The discovery of agriculture is the discovery that some aspects of Nature can be trivialized" (H.von FOERSTER, 1981, p.302).

He adds however: "While our preoccupation with trivialization of our **environment** may be in one domain useful and constructive, in another domain it is useless and destructive. Trivialization is a dangerous panacea when man applies it to himself" (Ibid).

As an example of trivialization he gives the way our system of **education** generally tends to uniformize and standardize students: "Tests are devices to establish a measure of trivialization. A perfect score in a test is indicative of perfect trivialization: the student is completely predictable and thus can be admitted into society. He will cause neither any surprise nor any trouble" (Ibid).

It seems however that the progress of **complex systems** toward a superior degree of non-triviality must be paid for by a trivialization of their **environment** (perhaps an unavoidable consequence of the **2nd. principle of thermodynamics**).

3650

TROPHIC NET

The net of **interconnections** in an **ecosystem** between the **resources** and their users (micro-organisms, vegetals and animals)

Practically in any ecosystem there is a multiplicity of resources (energetic, mineral, spatial) and users, most of them direct (or primary) users and various **levels** of indirect users. Many or these become in turn resources for the higher levels users, that must be considered as **predators**.

In a trophic net, the same resource can be used by different users and, conversely a specific user can use various types of resources.

The trophic net includes also **wastes**, that are generally **recycled** by some specialized users and are reincorporated as primary resources. The general motor of the net is **energy**, normally solar, in a direct or indirect way, but also sometimes geothermal.

The trophic net is in fact a complex **network** wherein some **correlations** are impossible or prohibited, and others possible in some ways and under some conditions.

It can be represented by **graphs**, more or less complex according to their **aggregation** or **disaggregation** levels.

Trophic nets are generally **nonlinear**. A vegetal or animal species can be eaten by different predators. Conversely the same predator may eat different preys.

This explains some failures in biological **control** of pests: An introduced species may very well switch to a prey different from the one it was supposed to feed on.

Also, the evolution of **populations** can turn **chaotic** if some **instability threshold** is crossed. In such a case also the global trophic net can be deeply- and sometimes, irreversibly- disturbed

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Most trophic nets have been deeply altered by man, who pretends to be the global and universal user, generally without a good **understanding** of their local and/or general conditions of **dynamic stability**. As a result, crashes and **collapses** could become inevitable and quite disastrous.

The whole subject has been exhaustively researched by some ecologists, as for instance the Catalan R. MARGALEF (1982)

→ **Entropy production; Feedback; Parasitism; Regulation; Sustainability; Symbiotic partnership; World Engine**

3651

TROPISM^{1) - 2)}

The **adaptive growth** or movement **response** of an **organism** toward or away of some **stimulus**.

This classical definition acquires new shades of **meaning** through the systemic viewpoint.

Tropism is not purely reactive and indistinct. D. Mc NEIL, for instance, writes: "A tree is a heliotrope and an hydrotrope, a **structure** and a **process** of substance and **organization**" (1993 b. p.8).

In systems, a tropism becomes more or less governed by the systems general **controls**: The tree reacts in an adaptive and variable way to sunshine and to soil moisture by regulating "global **flows** and counterflows" (ibid).

3652

TROPOS¹⁾⁵⁾

A greek word whose meaning is orientation, direction. The same general **meaning** appears in "**entropy**" and "**tropism**"

It has been introduced by the Greek psychiatrist and systemist N. PARITSIS in his study of **psychological contexts** (2000)

3653

TRUTH: (no definition given, of course... and quote marks "...." should be used)³⁾

According to general scientific common sense, truth is supposed to exist and to be attainable by the human **mind** in a kind of asymptotic way, through progressive refinement of **experience** and thought, including insight and **intuition**.

C.S. PEIRCE defined "truth" as "the opinion that would be agreed if scientific inquiry were to continue long enough, the opinion that can withstand all possible experiential evidence and full logical scrutiny".

This is quite similar to K. POPPER's later view on **knowledge** progress through "falsification", i.e. refutation of existing views after new experimentation.

Or, in logic, "truth is an **isomorphism** between **objects** and **symbols**" (G. HUNTER, as quoted by F. FRISCHKNECHT and J.van GIGCH, 1989, p.243).

However, in its classical meanings, **truth** presents a difficult, and probably unsolvable **ontological** question, because of our indirect **perception** of reality through a sensory equipment that filters it in a selective way.

In a quite more restricted and realistic vein, J.van GIGCH writes: "We conveniently sidestep the problem of defining what is meant by "truth" by saying that... solutions obtained from **problem-solving methodologies** shall be labelled "truths". Also to be valid, "truths" should:

"1. Meet the **objectives** of those who framed the problem,

"2. Meet **criteria** of internal **coherence**,

"3. Correspond as far as possible with perceived external reality,

"4. Be accepted by its recipients, and,

"5. Be morally justified" (1983, p.44).

van GIGCH himself however admits that: "The **issue** of what constitutes a "morally acceptable" solution is not treated here, but pertains to the broader question concerned with the Morality of Systems" (ibid).

Moreover, point 1 could lead to a kind of pseudo-**ontological** expediency.

Point 3 correctly denotes the **observer's** problem, while point 4, implies that "truth" is a matter of **consensus**, and thus at the same time, specific to some group, eventually modifiable and easily shifting (I.I. MITROFF & H.A. LINSTONE, 1993, p.24).

More generally, "truth" depends as stated by van GIGCH, from the **paradigm** in force and offers always cultural overtones.

Truth anyhow implies **coherence**, as it should be non-contradictory in itself, and in relation to the experimental **field**. This leads to the **constructivist** viewpoint according to which truth is progressively constructed by **observers**.

From a more Popperian viewpoint, and in J. MINGERS words: "The **process** of disclosure is never ending and, therefore, truth is not an achievable end-**state**, or correspondence of theory to the world, but a horizon never reached, a never-ending **process**" (1992, p.175).

Some consider truth as the complete reception of all existing world views.

Of course, such a view of truth is totally social and remains scattered among all individuals simultaneously.

This make it impossible to "pin it down" in a unified way because the global **synthesis** can never be constructed, nor in a static, neither in a dynamic form.

Moreover, contradictions or psycho-**semantic** incoherences between different views (for ex. between the mathematical view and the idealistic or religious one) makes any compositional view of truth totally unpractical.

→ "**Ontological agnosticism**".

3654

TUNNEL VISION¹⁾³⁾

A **metaphor** sometimes used to characterize the very restricted views of any specialist who is unable to take in account what does not enter in his disciplinary **frame of reference**.

Originally tunnel vision is an eye-sight pathology corresponding to a restricted **field of visual perception**.

In order to avoid tunnel-vision thinking, three different degrees of meta-disciplinary understanding can be defined, starting with **cross-disciplinarity**, further broadened through **multidisciplinarity** and at best **transdisciplinarity**.

Cybernetic and systemic **concepts** and **models** are essentially transdisciplinary. High-level **management** of **complex issues** should integrate multiple specialized aspects into transdisciplinary vision, as a way to obtain a sound and strong **coherence** in **decision making** and **action** and avoid unsuspected **perturbations** and contradictions.

→ **Blindspots, Clanthink, Environment, Observer, Perception, Underconceptualization**

3655

TURBULENCE^{2) - 4)}

The irregular motion of a fluid with local randomly fluctuating velocities and pressures.

D. RUELE (1991, p.70) explains that turbulence appears in fluids to which a **source** provides *growing quantities of energy*. In that case, according to L.D. LANDAU, a growing number of flowing **modes** in the fluid become excited. Turbulence than results of the **neighborhood** of stable and unstable **regions**". Turbulence was more recently described by F. TAKENS and D. RUELE as a **chaotic process** that could appear even in a **dynamic system** with no more than three independent **frequencies**.

I. SINAI states that, in turbulence: "... the movement is so complex that the notion of individual **trajectory** loses its sense and the only possible **description** is in terms of average characteristics". He moreover connects turbulence with **ergodicity**: "(in) **ergodic theory**, the fundamental problem is the analysis of the causes generating the emergence of statistical laws in **dynamic systems**" (1988, p.69).

At a **limit**, the movement even escapes from **ergodic** regularity and turbulence also becomes connected with the study of **chaos** and **chaotic systems**. K.DE GREENE states: "In systems **evolution chaos** and turbulence may well be prerequisite to **structural change**... **Short-term** turbulence can be part of **long-term evolution** toward a new **structure**".

DE GREENE applies his views to "societal or ecological **transition** or **transformation** (when) **perturbation** of the **environment** by human actions may lead to the development of new pockets of **order**, or new **autonomous systems**, in the **environment**" (1990, p.52-53).

All this is coincident with the **model** of **fractalization** of **vortexes** (vortexes within vortexes, within vortexes, etc...).

Turbulence can be intermittent. This happens as stated by M. FARGE: "... when the most active **regions** are not homogeneously distributed in **space** and **time**, but on the contrary appear as turbulent and violent "puffs". **Spatio-temporal** intermittence does lead to questioning the **homogeneity** and stationary hypothesis basic to the statistical theory of turbulence" (1992, p.239).

3656

TURING MACHINE²⁾

A **digital** machine with a supposedly unlimited **data storage** capacity, operating on one or more tapes each containing a numeral to produce a tape containing a numeral (After J. MYHILL, 1964, p.109).

D. RUELE describes the machine as follows: "(It) has a finite number of internal **states**: active **states** and a stop **state**. It does its work on an infinite ribbon, divided in a succession of squares (This ribbon serves as a **memory**). On each square on the ribbon a **symbol**, part of a finite **alphabet**, is written, one of these **symbols** being *void*. The TURING machine works by successive **cycles**, perfectly foreseeable. If it is in the stop position, it does nothing. Otherwise, the machine reads the square it occupies and, according to its internal **state** and to what it just read, will do one of the following:

- it will erase that which is written and write something else (Or the same thing) in the square;
- it moves to the next square, to the left or to the right;
- it changes to another internal **state**.

"If the new internal **state** is an active one, the machine will start a new **cycle**, according to the content of the new square and its new internal **state**."

"At the initial **state**, the ribbon contains a finite **message**, the **data message** (the rest of the ribbon is empty, i.e. made of squares marked with the *void symbol*). The machine starts at the beginning of the **data message** and... when it stops, it has written a new **message**, its answer or results **message**. The answer can be yes, or no, or possibly a number, or a longer **message**. It is possible to arrange a TURING machine to add or multiply whole numbers, or any other task that could be carried out by a computer".

In other words, the TURING machine is the universal theoretical model of the computer, in which an **algorithm** is used to process **data**, nothing more being needed.

RUELE adds: "There is no need for an infinity of different machines for different tasks, because there exists a *universal* TURING machine. To operate a specific **algorithm** on this universal machine, one must describe on the ribbon a **data message** that contains at the same time the **algorithm's description** and the specific **data** that should be processed" (1991, p.181-2).

G. KLIR states that, according to the CHURCH-TURING thesis: "... a TURING machine is taken to be a precise formal equivalent of the intuitive notion of an **algorithm**" (G. KLIR, 1991, p.128).

As may be observed, these elements correspond to the computer **program** and the **data store**.

The unlimited **storage** capacity, which for example "would be required to multiply two arbitrary large numbers" (Ibid) is however a practical impossibility.

M. BUNGE rightly observes: "... TURING machines..., being equipped with infinitely long tapes, are strictly speaking unrealizable" (1977, p.33). They are a kind of thought experiment... which however led to the whole of computer technique.

E. VACCARI and M. D'AMATO put it in a different way, but the meaning is more or less similar: "In a dynamic perspective, the Turing machine might be considered as a special limiting case of a discrete **time/discrete space model**, where the time between **state changes** is of no significance"(2000, p. 175)

3657

TURING STRUCTURES^{1) - 2)}

Emergent **heterogeneous structures** in a **homogenous distribution** of chemicals.

In his 1952 paper on "The chemical basis of **morphogenesis**", A. TURING showed that some chemicals, **homogeneously** distributed at first, may, by **reactions** and **diffusion**, lead to variations in their local concentrations, i.e. to **heterogeneity**, and form spatial **structures**.

This has been experimentally verified. As an **asymmetry** creating mechanism (rediscovered in 1976 by H. KUHN), it has a very general explanation power for the **morphogenesis** of **complex systems**, based on simple **evolution rules**.

As a result, similar **dynamic behavior** or **structures** may be found in very different systems, as for example in vegetal helixes (S. DOUADY and Y. COUDER, 1993).

3658

TURING's TEST^{1) - 3)}

The English mathematician A. TURING proposed a test to find out if a given **machine** can be considered intelligent (1950).

As a synthesis, in the words of P. DENNING: the test is "... an imitation game in which an interrogator asks questions of a human being and a **machine**; if the interrogator is unable to distinguish between the two, the **machine** passes the test and is declared intelligent. TURING replaced the question "Can a machine think?" (Title however of his quite more exhaustive 1950 essay - see 1956) with "Can the interrogator distinguish the two in an imitation game ?" because he considered the former question so imprecise as to be meaningless. His own opinion was that by the year 2000 there would exist **machines** capable of fooling the interrogator for at least five minutes in 30 % of the games played" (1990, p.100).

J. WEIZENBAUM's ironic book about his ELIZA program for psychological study, shows that the very acumen of the interrogator should also be tested in order to validate the test (1976).

At the time TURING devised his test, only sequential computers were in existence, and their potential **performances** were abysmally low, compared with the present ones. However, the **algorithmic** character of sequential computers **programs** still seems to rule out intelligence for this class of **machines**, even in chess playing or **expert systems**. However, the new **connection machines** and neural type **networks**, which are able to learn could easily reactualize TURING's test in a new way.

3659

TURNOVER¹⁾

The **process** by which the **elements** of a system are continually replaced by new ones of the same kind.

Such a replacement is a general feature of **living systems** and is operated through **self-catalysis** or **hypercycles**.

On the contrary, there is no turnover in **artefacts**.

3660

TURNOVER TIME¹⁾

The time needed for the total replacement of some **class** of **elements** or some stored **resource** in a system.

The turnover time depends on the internal **cycle** of **input** and **output**, correctly synchronized with the **level** of availability of the corresponding prime **resource** in the **environment**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

A well-regulated turnover time is necessary to maintain **dynamic stability**.

3661

TWO-BODIES PROBLEM²⁾

The two-bodies problem is the characteristic one of classical mechanics. It concerns the **deterministic interaction** of two bodies (in the celestial mechanics sense, for instance) reciprocally related through a simple **causal interdependence**. Such a problem is easily solved through a **differential equation** which states how certain quantities *and their rates of change* are related.

This kind of solution is however based on an implicate postulate, i.e. that such **relations** are not significantly perturbed by other "bodies". This is the famous lemma "...et ceteris paribus", which is generally invalid in the case of **complex systems**, even if and when **perturbations** are slight, some approximate solution may be found.

H. POINCARÉ was first to understand the nature of these difficulties as early as 1892, in his study on the **three-bodies problem**

3662

TYPES (Theory of logical)

→ **Logical types (Theory of)**

Table: see entry **Typology of Organizationally-Closed (Self-Referential) Systems**

3663

TYPOLGY OF ORGANIZATIONALLY-CLOSED (SELF-REFERENTIAL) SYSTEMS

John MINGERS proposed the following classification of organizationally-closed systems, all them being at least self referential (1999)

see table below

U

3664

UBIQUITY (Conceptual)¹⁾²⁾³⁾

The very general validity attributed to some **concepts and models**.

This new **meaning** for the term "ubiquity" has been proposed by M. BUCHANAN in a recent book (2000). He thus described the application of some concepts and models to a very wide variety of **situations or processes**.

He gives as an example the **self-organized criticality model**. This model has been used in many types of situations where a system is on the brink of some considerable sudden **change** or catastrophic **crisis**.

Examples are:

- the **distribution** of forest fires in Australia and the U.S.
- the distribution of measles **epidemics** on the Faroe Island in the North Atlantic

- the unstable situation in Europe in 1914 and the assassination of Arch. Franz Ferdinand of Habsburg which triggered World War I (Per BAK, 2000, p. 56-57)

Self organized criticality is only one of the new models of systemic character that appeared during the second half of the 20th C. in the course of a deep change of the basic **paradigm** about what scientific research does, and what is meant by "**explanation**"

It should be noted that in former centuries other concepts or models have also been ubiquitous, as for example **mechanistic determinism** in the 19th C. and first half of the 20th C..

Moreover, old concepts and models are not necessarily abandoned, but only reconsidered and put in a different perspective when new ones are introduced.

→ **Catastrophe theory; Chaos; Cycle; Cyclogenesis; Discontinuity; Powerlaws; Stability (Dynamic)**

3665

ULTRASTABILITY^{1) - 2)}

"The form of **stability** apparent in an **adaptive system**" (G. PASK, 1961a, p.115).

Adaptive systems possess **controllers** which are themselves adaptive, i.e. able to counteract a wide **variety** of **environmental** or **invironmental perturbations**.

Level in Boulding's Hierarchy	Relations that Characterise Level	Type	Characteristic	Example
1 Structures	Topology (Spatial)	<i>Self-referring systems</i>	Structural reference to self by position or symbolism (pictorial or linguistic)	"This is a sentence", Escher's "Drawing Hands", Magritte's "The Treason of Images"
2 Mechanisms	Order (Dynamic)	<i>Self-influencing systems</i>	Dynamic systems that involve circular causality and causal loops	Size and birth rate of population, inflation, the nuclear arms race
3 Cybernetic systems	Specification (Feedback)	<i>Self-regulating systems</i>	Maintenance of a particular variable at a particular level	Thermostat, body temperature
		<i>Self-sustaining systems</i>	All parts of the System are necessary and sufficient for operation of the whole, but do not produce each other	Gas pilot light in heating boiler, autocatalysis, nervous system
4 Living systems	Autopoietic relations	<i>Self-producing systems (autopoietic)</i>	Autonomy, the system both produces and is produced by itself	Cell, computer model of autopoiesis,
5 Multicellular systems	Structural coupling between parts	<i>Self-recognising Systems</i>	Systems that are able to recognise their own parts and reject others	Immune system within an organism
		<i>Self-replicating systems</i>	Systems that can build replicas of themselves	Organisms that reproduce, computer viruses
6 Nervous systems	Symbolic / Abstract relations	<i>Self-cognising systems</i>	Systems that generate cognitive identity through recursive neuronal activity	Animals with nervous systems. interacting symbolically
7 Observing systems	Self-Observational relations	<i>Self-conscious systems</i>	Able to interact with descriptions of themselves. The observer observing the observer	A person saying "I acted selfishly today"

From John Mingers – "Cybernetics and Human Knowing" – Vol 6(4) 1999

Ultrastable systems are able – up to a point – to change their internal **functional organization** and **structures** in order to adapt to external **disturbances**. However such changes must respect **global coherence**: “If the **whole** is at a **state of equilibrium**, each part must be in a **state of equilibrium** in the conditions provided by the others” (W.R. ASHBY, p.82).

And: “No **state** (of the **whole**) can be a **state of equilibrium** unless it is acceptable to every one of the **component parts**, each acting in the conditions given by the others” (p.83).

Ultrastability is thus the **oscillating** stability of the set of **critical** interconnected **variables** in a system, obtained through their repeated reciprocal **action**.

To demonstrate these characteristics, ASHBY constructed his well known “**Homeostat**”, an experimental cybernetic **machine** which shows an enormous **variability** potential, through **oscillations**... but tends to oscillating **stability** within **limits**.

In a **concrete system**, ultrastability requires **self-regulation** and therefore it must contain a good model of itself.

3666

ULTRAVARIABILITY ^{1) – 2)}

“The repeated and qualitatively heightened capacity for **change**” (V. KREMYANSKIY, 1969, p.132).

As he refers himself to **ultrastability** and **variability** as they have been studied by ASHBY, KREMYANSKIY writes: “It is known that the latter serves as a means for attaining **stability** (stabilizing **variability**); but, in addition (and this is far more important in biological systems), it serves as a means for developing new **forms** both of the species’ **stability** and also of the **variability** itself (**form-creating variability**). It is easily shown that an increased number of **components** (...) increases **variability** and has several other advantages” (Ibid).

The concept of ultravariability evokes also the swift and deep upheavals in **evolution**, to which S.J. GOULD and N. ELDREDGE give the name of punctuated **evolution**. The “increased number of **components**” could also be paralleled with the shaping of **dissipative structures** in systems submitted to **giant fluctuations**, **phenomenon** that may lead to the **emergence** of systems of a new type.

Ultravariability relates obviously to **phenomena** very different than those considered by the concepts of **autopoiesis** and **organizational closure**.

3667

UMWELT LEHRE ^{1) – 4)}

The specific **knowledge** any **living system** acquires about its **ambient** or **environment** (Umwelt, in German).

“Umwelt Lehre” leads to specific “**window perception**”, different for each **living system**.

This concept was introduced by J.von UEXKÜLL (see 1979). According to L.von BERTALANFFY: “It essentially amounts to the statement that, from the great cake of reality, every living **organism** cuts a slice, which it can perceive and to which it can react owing to its psycho-physical **organization**, that is the **structure of receptor and effector organs**” (1962, p. 73).

As stated by BERTALANFFY, von UEXKÜLL and KRISZAT have presented fascinating pictures how the same section of nature may look as seen by various animals. (see 1934)

“According to von UEXKÜLL’s expression, any **organism**, so to speak, cuts out from the multiplicity of surrounding **objects** a small number of characteristics to which it reacts and whose ensemble forms its “**ambient**” (Umwelt). All the rest is non-existent for that particular **organism**” (1962, p.73).

This Umwelt concept may seemingly be applied also to social systems, wherein a consensual psycho-mental Umwelt becomes absolutely dominant, and blinds the members of the group to anything else.

3668

UNBOUNDED SYSTEMS THINKING (UST) ^{1) – 4)}

An **Inquiry System** in which “everything interacts with everything” (I.I. MITROFF and H.A. LINSTONE, 1993, p.91).

In UST “all branches of **inquiry** depend fundamentally on one another, and... the widest possible array of disciplines, professions, and branches of **knowledge** – capturing distinctly different **paradigms** of thought – must be consciously brought to bear on our **problems**.

“In UST, the traditional **hierarchical** ordering of the sciences and the professions – as well as the pejorative bifurcation of the sciences into “**hard**” versus “**soft**” is replaced by a circular **concept of relationship** between them. In UST, everyone of the sciences and professions is considered fundamental; none is superior to or better than any other” (p.91).

UST introduces a **Multiple Perspective Method** (see corresponding heading), characterized by a triple perspective:

“T. The Technical Perspective
O. The Organizational or Societal Perspective
P. The Personal or Individual Perspective” (p.99).

The authors insist on the following aspects in using the **method**:

- “- Strive for a balance among T, O and P perspectives
- Use “good” judgment in selecting perspectives
- In obtaining **information**, recognize that O and P require greatly different **methods** than T

- Pay particular attention to the mutual impact, **interdependencies**, and **integration** of perspectives
- Beware of thinking statically in **dynamic environments**” (p.107-8).

And “UST is fundamentally a **transdisciplinary Inquiry System**. That is, UST does not believe that we can “solve” important problems within the current **structure** of the disciplines, professions, or the modern university. The various sciences and professions are the product of human **organization**. In this sense they are **artifacts**, not natural entities. As such, in working on every **problem**, we are also simultaneously working on how we organize ourselves to solve our **problems**” (p.109).

UST is yet one more example of the new focus on a **transdisciplinary** approach in order to avoid what WARFIELD call **underconceptualization** and de ZEEUW, **invisibility**.

3669

UNCERTAINTY ^{1) – 3)}

The impossibility to reach a perfect **knowledge** of any **complex system** or **situation**.

The uncertainty problem came slowly to pervade the whole field of **complexity**. This is normal, considering that the multiplicity of **initial conditions** in **complex systems** leads to **chaos** and a high degree of **unpredictability**.

It offers different facets, related for ex. to the interrelations between **levels of complexity** and the various limitations to **perception** and construction of mental **frames of references**.

The problem is also associated with the general conditions of **modeling**, as shown by G. KLIR, within the frame of his **reconstructibility analysis**. (1991, p.350; 399-401)

E. MORIN distinguishes four different shades of uncertainty

1. Brain-mental uncertainty, which results of the **process of perception**, and **modelization of “reality”** by the **brain**
2. Logical uncertainty according to which some **ambiguity**, **complementarity** or even contradiction seems to be inherent to our **reconstruction of reality**. BOHR’s and the Copenhagen interpretation in micro-physics is an example
3. Rational uncertainty due to the **fuzzy** border between rational **explanation** and fake or uncritical rationalizations
4. Psychological uncertainty due to our necessarily limited **awareness** of the soundness of our own mental **processes** (E. MORIN, 1999b, p. 82-84)

3670

UNCERTAINTY (Chaotic) ^{1) – 2) – 3)}

P. COVENEY, in accordance with Prigoginian thermodynamics of **systems far-from-equilibrium**, alludes to “... a new kind of uncertainty principle that applies to chaotic dynamical sys-

tems. This new principle shows that complete certainty of the **thermodynamic** properties of a system (through **knowledge** of its irreversible age) renders the reversible dynamical description meaningless, whilst complete certainty in the dynamical description similarly disables the **thermodynamic view**" (1990, p.52).

Would chaotic uncertainty not be an obliged result of **chaotic determinism**, which maintains a global **determinism**, but does not allow any more a precise **predictability**?

3671

UNCERTAINTY (in psychological sense)^{3) - 4)}

Any **interaction** between an **observer** and what is observed, changes both.

D. Mac KAY writes: "The second type of "absolute" uncertainty attends our **knowledge** of one another in interpersonal **dialogue** (as distinct from detached physical **observation**. Quite independently of any physical **indeterminacy** of our **brain** mechanism, this uncertainty reflects the fact that, in the public calculus of two or more persons in **dialogue**, *no valid definitive prediction exists* for their detailed future **behavior**. In this **relationship** the action of each has an irreducible (potential) selective **information-content**, for his fellows as well as for himself" (1969, p.154).

Here again, like in the case of **indeterminacy**, it is arguable if every individual (and every group) can ever act outside the global **determinism**, as the product of education and instruction within a specific culture, not to speak of the general human conditionings.

3672

UNCERTAINTY (Measure of)²⁾

"The average number of **binary decisions** a decision maker has to make in order to select one out of a set of actually exclusive alternatives" (K. KRIPPENDORFF, 1986, p.77).

This number is the logarithm of the number of possible alternatives.

According to G. PASK: "Given a well-defined **set of elements**, it is possible to measure the *amount* of uncertainty with reference to this **set**. The **reference frame** provides a **set of states**, hence a measure of uncertainty is possible and is called the *variety* of the **set**. ... **Information** and uncertainty, if expressed in an additive form as logarithmic measures, are very simply related indeed:

Uncertainty = - Information" (1961, p.26).

This is, of course, the quantitative aspect of uncertainty, based on the hypothes of a **consensus** on their **data** among the different **observers**. PASK himself has been quite concerned by this **consensus** problem.

3673

UNCERTAINTY PRINCIPLE^{2) - 3)}

"It is impossible to simultaneously measure the position and the momentum of atomic particles with an arbitrary degree of accuracy".

K. KRIPPENDORFF writes: "The principle recognizes the fact that, on the atomic **level**, any **measuring process** involves **energy** which by necessity interferes with the **energy** measured" (1986, p.78). This is because both energetic actions are at more or less the same **level** of intensity.

It would be advisable to better distinguish **indeterminacy** from uncertainty.

The first word relates more closely to any **situation** in which it is impossible to know exactly and simultaneously two (or more) characteristics of an observed **object**, especially in the realm of micro-physics.

Trying to better the instruments of **observation** is practically useless, as noted by H.H. PATTEE: "... the more you describe the measuring device, the less effectively it measures or describes the system" (1977, p.262).

On the other hand, HEISENBERG himself speaks also of an "Uncertainty Principle" (not merely **indeterminacy**), which introduces obviously an epistemological problem. J.C. TABARY states: "No **information** about Nature "in itself" can reach us, but merely **informations** on our own deformation when in contact with Nature: Nature's image becomes the image of our physical relation with Nature" (1989, p.278).

3674

UNCERTAINTY SET^{2) - 4)}

The **range** of expected future **disturbances** that may affect a system.

This notion has been enunciated by M. MESAROVIC et al in a study about the satisfaction conditions in biological systems (1973, p.68).

It could also probably be introduced in economic and social systems and in industrial and business enterprises.

The definition of an uncertainty set is necessary for an optimum calibration of the **regulators**. It remains however always somewhat conjectural.

3675

UNCOMPUTABILITY THEOREM²⁾

"Given a **program P** and an **input data set I** there is no way in general to say if P will ever finish processing the **data I**".

This theorem was enounced in 1936 by A. TURING and is closely related to the **incompleteness theorem** of GÖDEL.

It relates also to what is known as the **halting problem**, thus formulated by J. CASTI: "Is there a *general algorithm* for determining if a program will halt ?" (1990, p.346).

While the problem has some partial and specific solutions, TURING demonstrated that no general one does exist.

As observed by A. CHURCH, uncomputability reflects **undecidability** and non-**recursivity**.

3676

UNCORRELATED EXTREMES (Law of)^{2) - 4)}

"No matter what the complex **issue**, and no matter what the **group** involved in its study, the *initial* aggregate **group** opinion concerning the logical **pattern** of the factors involved in the **issue** and the *final* aggregate **group** opinion concerning the logical **pattern** of the factors involved in the **issue** (i.e. the views at the two extremes...) will be uncorrelated; showing that significant **learning** takes place through the application of the **Generic Design process**" (J.N. WARFIELD, 1995, p.145).

The law is evident for anyone who has once participated to a **group** discussion. The point is that its practical consequences (the "**Babel tower effect**") are generally not perceived, and still less taken care of.

Still more important is that WARFIELD's **methodology** of **Interpretive Structural Modeling** through **Nominal Group Technique** permits the discovery of the whole field of opinions, as well as their relative weights. It thus opens the way to a thorough evaluation by the **group** of the whole **range** of opinions, avoiding resentment from those who otherwise should not have been given a voice. In this way, a base for real **consensus** can be constructed.

3677

UNDECIDABILITY^{1) - 3)}

An ambiguous **situation** in which it is not possible to decide the **truth** of a proposition or to take a definite stand in a **decision process**.

J.van GIGCH writes: "Undecidability existing at one **level** of **language** can only be removed by the use of a **metalanguage**" (1990, p.128).

This is clearly a generalized consequence of GÖDEL's **Incompleteness theorem**, and is also reflected in A. CHURCH thesis according to which "decidability is equivalent to **recursiveness**, which is equivalent to computability" (as quoted by R. SCHOENFELD, 1949, p.88).

3678

UNDERCONCEPTUALIZATION^{3) - 4)}

The insufficient **understanding** of complex **issues** by any single individual or **group**.

J. WARFIELD, who introduces this concept distinguishes three different aspects of under-conceptualization:

"1. Structural underconceptualization means that the **organization** of the **information** about a given issue is insufficient to enable the important **patterns** to be inspected... We can say... that ordinary **processes** omit recognition and interpretation of the **cycles** that are at work in a given **issue**...

"2. The second aspect... stems from the normal absence of any sense of length of logic (note: i.e. interconnected logical sequences)

"3. The third aspect arises by ignoring in ordinary approaches to **issues** the human limitations on working mentally with **information**, which are well known from the work of MILLER, SIMON, and others, but which seem systematically to be ignored in **systems analysis** and **design activity**" (1991, p.200).

3679

UNDERCONCEPTUALIZATION (Law of structural)^{1) - 2) - 3) - 4)}

"No matter what the complex **issue**, and no matter what the **group** involved in its study, the outcomes of ordinary **group process** (i.e. the **process** in which computer support for developing the formal logical **structure** of the issue is lacking) will be structurally underconceptualized (as evident, for example, by the lack of delineation of the **cycles** and of any **structural connections** among them)".

The law merely states the foregoing WARFIELD's explanations about underconceptualization.

3680

UNDERCONNECTANCE^{1) - 2) - 4)}

A characteristic of "a system which is very susceptible to intrusion since there are insufficient **connections** between the **parts** for the system to maintain integrity" (T.F.H. ALLEN & T.B. STARR, 1982, p.280).

This definition seems to apply nicely to overextended systems.

An obvious application can be made to ancient empires whose overextended **communication** lines combined with the resulting **time lags** in the **transmission** of **information** tended to push them toward their disintegration, mainly through the intrusion of alien groups and the **emergence** of local powers.

3681

UNDERCROWDING²⁾⁴⁾

The situation where an insufficient **density** of **population** undermines social **stability** and even possibly **survival**

A minimum number of individuals in a given **environment** seems to be necessary for triggering **social behavior**. In a recent paper A. BARNET notes for example that "flamingos or

penguins won't breed unless they are surrounded by other copulating pairs"(2001, p. 38) Undercrowding seems to induce the following negative **effects** on societies:

- possible loss of genetic and behavioral **variety** (In societies, also loss of **cultural** and **semantic** variety)
- loss of **herd** protection effects
- lessening of transgenerational **learning**
- lack of **communication** and loss of **information**
- danger of destructive episodes due to reduced **adaptability** (the Fuegians extinguished by a succession of negative factors as epidemics, alcoholism, etc)

A comparison with the **situation** of **overcrowding** shows that any **population** must remain in a defined **dynamic stability** relation with its probably variable **environment**. Such stability corresponds to also defined **levels** of maximum and minimum **density**, within a sustainable **range of fluctuations**

Undercrowding effects were first studied by W. ALLEE in the U.S.(1951) and are now known as "Allee effects"

3682

UNDERLOAD STRESS^{1) - 2)}

Stress induced in a system by insufficient **inputs** of **energy**, **matter** and/or **information**.

N. PARITSIS comments: "If the **environment** is too simple and remains unchanged, the **organism** has very little to learn, meaning that simple **environments** also inhibit **learning** and are producing underload stress" (1992, p.38).

For comparison, see "Overload".

3683

UNDERSTANDING³⁾

The ability to interrelate **informations** within more general embracing mental **frames of reference**.

Understanding leads to the creation of **knowledge**, which consists of systems of coordinated **informations**, which can be put to use in the following ways:

- obtain working interpretations of the **significance** of interconnected **informations**.
- discuss the **validity** of such interpretations.
- correct and expand already existing **frames of reference**.
- Use **knowledge** obtained in this way to seek workable alternatives on issues, to - further better **design** of projects and to make **decisions** based on well informed - **choices**.

There is a specific form of systemic understanding which corresponds to the use of **frames of references** allowing interpretations of **nonlinear systems**.

In relation to **conversation** and **consensus** and according to H.von FOERSTER we can only "construct our own understanding of the other's understanding" (1993, p.110)

We should thus have to rely on the other's agreement on what we express about our understanding of him/her... and reciprocally. This is indeed a shaky ground for reciprocal understanding and consensus... but it is the only one we have!

In a quite different vein, R. GLANVILLE also explores what we do mean by "understanding". He writes: "We are different: I can never have your understanding of your understanding, which is precisely not your understanding)" (2001, p. 145-46).

The meaning of "conversation" in Pask's sense is the reciprocal polishing of our respective understanding. Nobody can better understand anybody else without a conversation in which each one testifies how he/she understands the other's understanding.

The typical dialogue would be:

"-If I understand you well, you mean that..."

"-Well, more or less if interpreted in your terms. But what do you mean when you say that my opinion is that...?"

Of course that type of dialogue can easily become a hopeless **semantic** and mental circular labyrinth. This can be avoided only between good-willed people in search of sincere and useful reciprocal **communication** through progressive mutual spiraling **adjustment**.

It is however a very good cure to intolerance, fanaticism and even simple stupidity

In a still more subtle way, understanding refers to the general **implicit meaning** of what we are perceiving and cannot (or cannot yet), or do not want to express as knowledge in a specific **language**.

In KRISHNAMURTI's words : " In the interval between words, between thoughts, comes understanding and...this interval is silence unbroken by knowledge"

3684

UNEXPECTEDNESS as a measure of negentropy^{2) - 3)}

Mac KAY defines unexpectedness as "the average logarithm of the improbability of a **message**:

$-\sum p_i \log p_i$ " (1969, p.57).

As unexpectedness is a measure of improbability, it is the contrary of high probability, which is closely related to nearly homogenized systems after a considerable and not compensated production of **entropy**.

It may thus be considered as a measure of **negentropy** in systems wherein the production of **entropy** has been coupled with **structuring dissipation** to lead them towards the **emergence** of higher **complexity**, i.e., **heterogeneity**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3685

UNFOLDMENT¹⁾

The gradual **development** of a system's internal **order**.

In **complex systems**, since their very genesis, there is an implicit (or in D. BOHM's terminology "implicate") **order**, which becomes revealed as the system grows. Viewed from this approach, as stated by F. DAVID PEAT: "The universe is sustained through an act of creative unfoldment in which no **order** is absolutely fixed, but is able to respond to an ever-changing **context**" (1987, p.215).

This is a very general property of biological, social or conceptual systems. An interesting example is the development of a musical fugue.

Unfoldment is a possibility implicit in **organizational closure**.

However, unfoldment is never total, since it depends on the external **constraints** that the system will meet during its **development**.

3686

UNIDIRECTIONALISM¹⁾²⁾

A basically **top-down communication process**.

Any process wherein the receiver of the **message** is not able to give any **feedback** to the emitter is unidirectional and tends to have **conditioning effects**.

This applies for ex. to any type of cathedratic teaching, to written, broadcasted or television **information**, and also to computer transmitted **information** when the receiver is not supposed to discuss or elaborate on what is mailed to her/him.

It may be useful to a point in teaching, but it is frequently a tricky and objectionable **process** as when used for propaganda and even in many cases to publicity

→ **Multidirectionalism**

3687

UNIFICATION PROBLEM²⁾³⁾

The unification problem emerges from our general (cartesian) **methodology** to fragment **complex systems** in severed **parts** in order to better understand their nature.

However such "cutting to pieces" destroys, or at least, reduces our understanding of the **whole** system.

L. LÖFGREN (2000, p. 15-20) sees the problem mainly as a result of our **languages**, which is clearly true, at least in western cultures

He sees any low **fragmentation** as unavoidable and even proposes it as a fundamental concept for General Systems. He offers as "a first natural proposal...an *interdisciplinary* understanding"(p. 15). This may seem insufficient in order to restore an integrated holistic view, as it most generally amounts merely to a "collage".

This editor believes that we should reach for *transdisciplinarity*, i.e. creating a language of systemic **concepts** and **models**, mainly for the purpose of **wholeness understanding** through the study of **links** and **relationships**.

→ **Linguistic closure**

3688

UNION EUROPEENNE DE SYSTEMIQUE¹⁾

The Systems Science European Union (UES) started in 1989. It is an European association of national systems science societies, including at date, the Czech, English, French, Greek, Italian and Spanish Systems Science societies. The Union is open to all European national societies. Main goals are: promotion of the systems sciences and coordination of activities within an European plan: schools, meetings, debates, teaching and the publication of the Revue Européenne de Systémique: res-systemica available at: www.res-systemica.org

3689

UNION OF INTERNATIONAL ASSOCIATIONS¹⁾

This Union was created in Brussels before the first World War. It became very active from the 1970's on under the impulse of his General Secretary A. JUDGE, who publishes and updates a very useful Encyclopedia under the title: "World Problems and Human Potential" (Saur Verlag, München)

3690

UNIT (Behavioral)²⁾

A **population of elements** ("behavioral atoms" in J. HOLLAND's terminology) in an **adaptive system** "which generates **action** sequences, and is modified on the basis of the outcome" (1992, p.155).

The behavioral unit is the very basic adaptive device in the system. Its **behavior** depends on its reactions to registered **environmental effects**. However these reactions depend also on the internal **behavioral rules** of the system.

HOLLAND's behavioral units seem to be indispensable for **parallel distributed processing**, as described by Mc CLELLAND et al., (1986)

3691

UNIVERSAL PROPERTY²⁾

"A property that does not change under a re-normalized **group transformation**" (G. MAYER-KRESS, 1988, p.357).

The author states: "... the base idea is to determine how a given system behaves under a **transformation** which changes the **scale** and also perform a **symmetry** operation (Ibid).

He proposes the interesting idea of an inverse reconstruction of the Cantor segment, starting from the "dust" of points obtained in the Cantor set after **fractalization**. In this way "more and more of the gap are covered with solid intervals... (and finally) we arrive at only one single segment interval" (Ibid).

In this way a complex **whole** is constructed by the sole use of one specific, well defined iterative **transformation**. This could be done also, for example, with the **WEIERSTRASS function** and lead to the idea that **complexity** may result from the **scaling, level by level**, of some very simple **rule** or **rules of transformation**.

→ **Game of life; Reconstructability analysis; Stigmergy**

3692

UNIVERSE^{1) - 3)}

The totality of which an **observer** is aware of.

J. L. DESTOUCHES writes: "Any system is a **whole** always contained in another **whole** called "Universe" or **environment**" (1947, p.196).

Of course, the "universe" selected by the **observer** at one moment is less than the total universe that he/she could observe, and this in turn is less than the total existing universe.

Any **observer** has "**blindspots**". Nobody is capable to observe more than a very small **part** of reality, of which many aspects remain hidden to any of us.

A very important aspect of systemic training is covering the need to understand our perceptive and conceptual **boundaries** and to know the permanent "**invisibility**" (G.de ZEEUW) for us of many features within the real world.

As emphasized by the French economist J. FOURASTIÉ, there is something worse than ignorance and it is ignorance of our ignorance.

3693

UNIVERSE, from LAPLACE to chaos³⁾

The French mathematician and astronomer P.de LAPLACE proposed a "clockwork" **model** of the universe through the hypothesis according to which "one who should know the positions and movements of all the bodies of the universe at one instant, would be able to predict their positions at any moment of the future". This view seemed indeed strongly confirmed by some spectacular astronomical discoveries during the 19th century based on this type of deterministic calculus.

However, POINCARÉ showed in 1889 that some quite simple astronomical problems (the famous **three bodies problem**) could not be rigorously solved.

This was the starting point of **chaos theory**. In P. DAVIES words: ... even one such **chaotic system** would rapidly exhaust the entire Universe's capacity to compute its **behavior**. It

seems then, that the Universe is incapable of digitally computing the future **behavior** of even a small **part** of itself, let alone all of itself. Expressed more dramatically, the Universe is its own fastest simulator" (1990). R. JENSEN expressed the same idea (see hereafter).

3694

UNIVERSE (Relational) ³⁾

This concept is introduced by M. MARUYAMA who writes: "In contrast to the classificational universe which is substance-oriented, the relational universe is **event-oriented**...

"Instead of the preoccupation with the ontological or causal priority among beings, in the relational universe, the mutuality of **interactions** predominate. "Definition" is not given by **categories** and subcategories, but by **interactions** and **interrelations**... This should not be misconstrued as "dialectic opposition". Its mode is **complementarity** and harmony, fusion rather than division...

"The **relations** are many-sided, mutual, situational, and not governed by the principle of subordination, superordination and paraordination. The relational universe does not establish **hierarchy**" (1966, p.57-58).

These views are closely related to the **deviation-amplifying models** of the same author.

3695

UNPREDICTABILITY ^{1) - 3)}

A total or relative impossibility to predict the future **behavior** of a **complex system**.

Most importantly, I. PRIGOGINE and I. STENGERS observe that "... the existence of **chaotic systems** transforms the notion of unpredictability, frees it from the idea of a contingent ignorance, that a better **knowledge** would surmount, and gives it an intrinsic **meaning**" (1992, p.81).

While singled out **processes** within a stable **environment** are generally **linear** or reducible to **linearity**, **complex systems** exhibit normally a **chaotic behavior**, which makes them more or less unpredictable, due to constant interferences between **processes** of different **periods** resulting for a multiplicity of simultaneous **initial conditions**.

R. JENSEN states: "Another manifestation of the unpredictability of **chaotic dynamical systems** is that the **time-evolution** is computationally irreducible... There is no faster way of finding out how a **chaotic system** will evolve than to watch its **evolution**. The dynamical system itself is its own fastest computer" (1987, p.179).

While this is true in theory, *imperfect* predictability is feasible: most systems have some characterized **dominant periods** which remain more or less observable, even if they are to some measure deformed and obscured by **chaotic** ripples brought about by various or even

numerous other **cycles** of lesser weight, as well as subject to sudden and massive **trend variations**. In short, some **patterns** remain more or less visible.

→ **Action (ecology of); Forecasts (limits to)**

3696

URBAN ECOSYSTEMS ⁴⁾

"Ecosystems with **components** mainly of urban built characteristics and with relatively high **densities** of human **populations**" (UNESCO – UNEP glossary, 1983, p.28).

The glossary comments: "It is recognized that urban ecosystems are not self-sustaining or complete ecosystems and are dependent on outside **sources** and factors" (Ibid).

3697

URBAN ENVIRONMENT ⁴⁾

"The resulting effects and **interrelationships** of human **population** concentration, the built **environment**, and the biophysical **environment**" (Ibid).

The UNESCO glossary observes that "city dwellers often view the urban built **environment** as the only "environment", and it consequently advocates "the need for environmental education to encompass the entire environment..., i.e. a **holistic** view of the complete environment" (Ibid).

3698

USEFULNESS ¹⁾

That which can **changes** a **situation** in an advantageous manner.

Such a definition is obviously ambiguous: what should be advantageous is a matter of **criteria**. Moreover, a wide **variety** of **criteria** could be considered: economical, social, technical, etc..., or personal, groupal or general.

In accordance with different **criteria**, **decision makers** may find it difficult to make a globally satisfactory **choice** between different useful, but sometimes irreconcilable options.

Finally usefulness in systemic terms should be judged according to the vantage to the system in general (global **optimization**, **long-term survival**), and the **maintenance** of its supporting **environment**. Such judgment can be reached only by an integrated systemic approach.

3699

USOMID

"The Slovene abbreviation for: Oriented, Wholistic, Co-operative and Organized Invention and Innovation Activity of the Masses" (M. MULEJ, 1986, p.151).

MULEJ describes as follows the ten components of the USOMID methodology:

"1. Education for creative **co-operation** with short courses ... and practical experience;

"2. Development of "being considered" as the basic value guiding people toward **creativity**, and so a precondition for their motivation for creative **co-operation**;

"3. Charting the **processes** which take place in the **organization**, in **co-operation** with the workers who do them and know most about them, including also the **processes** of creative work, in **framework programs**, compiled in a "programmotheque";

"4. Possibly, a computer-aided programmotheque, deeper in quantitative insights into the basic **process** (supply-production-marketing)

"5. the USOMID/SREDIM procedure as the method of creative **co-operation**;

"6. Deliberate seeking for possible **changes** as the basic orientation of such a creative **co-operation**;

"7. Application of **management by objectives** which include support and constant care for creative **co-operation** as a whole and its **strategies** for innovation with **objectives** of every (middle) manager and foreman:

"8. Proceeding from the general insight toward details in order to fight unavoidable one-sidedness by interlinking the specialists' **viewpoints** into a (dialectical) system of all essential viewpoints;

"9. Studying the **processes** and their **environment**, not the organizational **structure** and the **hierarchy** of subordination, and following the links of their steps with the "causes tree"

...

"10. The USOMID circle as the organizational possibility for a permanent creative **co-operation**" (p.152-3).

In some way, USOMID seems to be related to JOHANNESSEN's **heterarchical** concept of the **organization**.

For details on this **methodology**, practiced in Slovenia since 1980, see MULEJ's bibliography in the referenced paper.

A quite complete description of the USOMID **methodology** has been made by T. ECIMOVIC et al., in their 2002 study of "System thinking and climate change", published at the Maribor University in Slovenia (2002, section 4.5)

3700

UTILITARIANISM in a systemic perspective ¹⁾³⁾⁴⁾

Utilitarianism is generally seen as an individualistic world view. However, if the individualistic view is irrestrictively adopted, it may easily lead to wilful ignorance or negation of social utility. Such a view, in turn, easily leads to individual **actions** which directly or indirectly undermine the very conditions that permits individual utility itself. On the contrary, the ignorance of the competitive **role** of the individuals leads to the impossibility to discover new **behaviors**, possibly valuable for the **whole group** or society.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Thus the systemic view should aim at a better harmony between the individuals (i.e. belonging to the **parts**) view and the systemic view (i.e. social, i.e. on the whole)

J. BRYANT debates these aspects (1991, p. 176-180, and 184). He enounces for ex. the following theorem: "A necessary and sufficient condition for the maximization of expected group utility is the free flow of **information** among members of that group"(1991, p. 177)

Curiously altruistic utilitarianism can be used in two different ways:

- closely practiced, as for ex. in mafias
- widely practiced, as through utopian **ideologies**

This shows the fuzzy character of this concept, and the need to avoid simplistic views.

→ **Behaviorism**

V

3701

VALIDATION ³⁾ - 4)

The (mostly consensual) **process** of recognizing the soundness of a theory, **method**, concept or **model**.

Validation is always referred to a prior system of values or **concepts**, accorded within an **epistemic community** through explicit or implicit **consensus**.

"Truth" or "reality" can never be guaranteed in an absolute way by any theory, concept or **model**, even if constantly and carefully re-validated (see "**ontologic skepticism**").

J. WARFIELD enounced a "Law of Validation": "The validity of science depends upon substancial agreement within the scientific **community** of meaning at its highest grade, i.e. meaning attained through **definition by relationship**". As observed by WARFIELD himself. this "is a necessary, but not in general sufficient condition for scientific validity". One of the main difficulties is that "... interpretations are crucially dependent on **language**. The **language** itself is one of the implicit aspects of **systems thinking** and of science in general" (1988, p.337).

Other problems are:

- **Consensus** on new **concepts** or **models** can be long delayed by a dominant **paradigm** (Remember WEGENER about continental drift and MILANKOVICH about climatic cycles).
- **Consensus** is frequently more easy on abstract formalizations and **models** – logical or mathematical – than on practical applications.

3702

VALIDATION (Model) ²⁾³⁾

J. CASTI enumerates as follows some criteria along which the **validity** of any kind of models should be established (1997, p.11):

"**Operational**: Is the model able to provide answers to the questions for which it has been built?"

"**Empirical**: Does the model agree with observed **data** that are relevant to the problem under consideration?"

"**Theoretical**: Does the model contradict any established **theories**?"

"**Consistency**: Does the model contain any logical contradiction?"

"**Faith**: Do specialists in the area being modeled agree that the model produces believable results?"

"**Testing**: Can the model be tested in the real world?"

Of course, some new models may "contradict established **theories**". In such cases, we need a thorough discussion to evaluate if there are really contradictions and, if so, to find out their causes.

As to the "believable" character of the results, it depends on the "**beliefs**" of the evaluators, whose **frames of references** should be clearly stated and possible also re-evaluated. Let us remember of the general and protracted opposition of mainstream geologists, from the 1920's on, to WEGENER's views about continental drift, later to be confirmed by plate tectonics.

Invalidation, as well as validation, must always be deeply justified.

3703

VALUATION TERMINOLOGY ¹⁾²⁾³⁾⁴⁾

Many usual qualifying terms should be closely scrutinized from a systemic viewpoint because they introduce implicit cultural biases, which remain hidden to most of the users.

Examples are words like "acceptable, admitted, normal (or abnormal), recognized, relevant, satisfactory, useful (or useless)", etc...

Any research, specially directed at **human systems**, should define clearly to whom, in what cases, in which places and times something is "acceptable", etc...

In system's **modelization** of any type **fuzzy** valuations are at the same time very difficult to avoid, and in case of use, difficult to place in perspective and, still more so, to quantify when needed.

Many **issues** are thus obscured and, in cases, this can lead to serious errors and abuses.

3704

VALUE (Economic) ⁵⁾

The monetary pricing or **assessment** by a specific society at a specific time of a natural or artificial item.

While the fact is generally understated or ignored, economic value is obviously always the result of a dominant - but variable - cultural or social **consensus**, as shown for ex. by some extravagant speculation episodes, like the tulip craze in Holland some centuries ago.

Inversely, some material **resources** that were without economic value in the past, may acquire one as a result of some technological advance. The case of oil is a striking example. Genes are now similarly acquiring an economic value (D.F. VIVIEN, 2000, p.88).

According to VIVIEN, economic value can be considered from three different angles:

- value for what kind of use
- value for whom
- value for what **time**, i.e. present or some short or long time future.

However, the notion has many times a controversial relation with ethical and social value, much more difficult to assess. This may lead to deep and conflictive changes in **social systems**.

A case is the controversy about the value of the planetary **ecosystem**, or planetary **commons**, which pervades all debates about preservation or conservation of natural **resources** of all kinds.

3705

VALUES ³⁾ - 4)

The basic **rules** which govern the individual and collective **behavior** of the members of a **human system**.

According to the "Glossary of environmental education terms" of UNESCO – UNEP: Values are "formed by **groups** of attitudes which cluster. Values produce **behavior** as contrasted to attitudes which represent a behavioral disposition potential or tendency. Values are individual or collective conceptions (based on) emotional, judgmental and symbolic **components** of that which is of worth, important, or desirable" (UNE Glossary, 1983, p.29).

This formulation is somewhat objectionable: in effect, values are proper to *groups of people* whose attitudes become clustered, i.e., values are **abstractions** if not translated into **behavior**.

For N. RESCHER, values are instrumentalities for reasoning about alternatives (Quoted by K. SAYRE, 1976, p.185). SAYRE adds: "What makes values important principles of social **cohesion** is that they contribute so effectively to the formation of personal **habits**. The emphasis upon reasoning is understandable, however, in that values also play an important role in the

public justification of problematic courses of **action** and the values supporting it must be understood commonly by all parties involved" (Ibid).

A. LASZLO explains the mechanism of values **action** on individuals and **groups** in the following way: "... **cognitive maps** must involve values. Values are **symbols** that serve to record **phenomena** and that catalyze **reactions** to them. On an individual **level**, **cognitive maps** are conditioned by the values and beliefs that are dominant in society at the time. By internalizing values derived from cultural **contexts**, individual **maps** incorporate a certain amount of developmental leeway. Values encourage repeating **behavioral** sequences, forming stereotypes, and performing rituals. Much of the **information** in these media, **information** on which individual **maps** depend, is transferred from others. Thus human mental **maps** can be constructed without direct experience. The nature of these **learning processes** contributes to making our **cognitive maps** socially constructed realities.

"Within a given **culture**, values and beliefs are relatively coherent. As a result, it is possible to talk about a collective or societal **cognitive map** of the **environment** (social, cultural, as well as natural). It describes the dominant **world-view** in a given **culture** at a given **time**" (1993, p.318).

Values are the basic references for **regulations** in any fundamental aspects of human systems. They are the sources of **norms** and standards.

G. VICKERS states: "The problems of the traffic **regulator** are set by the **standard** of congestion, which is regarded as unacceptable. Without such a **standard** there would be no problem and nothing to regulate" (1967, p.60).

Of course, this would mean radical anarchy and could make life downright impossible for many people.

Thus: "All **regulation** depends on setting standards by a **process** of human valuation" (Ibid).

Such a **process** can be successful only through open or tacit **consensus** by a clear majority of the interested people. Any authoritarily imposed standard brings some kind of **stress** in the social fabric.

Consensus, in part, is in turn based of more general and permanent cultural values. For this reason, we should pay much attention to the following comment by VICKERS: "We now seem to be approaching a point at which the **changes** generated within a single generation may render inept for the future the skills, the institutions and the ideas which form that generation's main legacy to posterity and the next generation's principal heritage" (Ibid, p.61).

This is a very serious problem, because values are necessarily transmitted from generation to generation through **education** and **training**.

In other words, our traditional social **regulators** are at great risk... as well as ourselves, as a result.

This becomes still clearer when, as stated by F. PARRA LUNA: "... the ideal system of values ... (is) defined by those in command" (1993, p.423).

Formerly, values **stability** was guaranteed by the **autopoietic** way those "in command" received their values through traditional **education**. Their leeway for interpretations was very limited. But this is not anymore the case...

3706

VALUES (Organic and mechanistic)^{1) - 3)}

P.L. BEUKEMA proposed the following comparative taxonomy of organic and mechanistic values (1974, p.255, hereafter reproduced in a shortened form):

ORGANIC	MECHANISTIC
Reward and recognition	Reward or punishment
Warmth and support	Formal support and objectivity
Task clarity and flexibility	Hierarchy and rational organization
Individual responsibility	Restrictive supervision
Confrontational conflict management	Forced conflict management
Collegial-supportive authority	Autocratic-custodial authority
Multi-dimensional communication	Bi-dimensional communication
Growth and innovation	

3707

VALUES TRANSMISSION MODES^{1) - 4)}

The transmission of values is basically a social **autopoietic process**: Values constitute a global **code** of prescribed or prohibited **interactions** within society. Their permanent use is the constant reconstruction of these **interactions** through the conditioning of the individuals whose **role** is to permanently reconstruct the social fabric.

A.P. VARDOMATSKY enumerates the following social and psychological **mechanisms** responsible for values transmission:

"- Social expectations (which)... in a close **environment**... offers a personality a certain **set** of social **roles**...

"- Suggestion... the **transmission** of **information** based on the uncritical attitude. Here the authority of the one who suggests is necessary

"- "Infection"... the **transmission** of certain emotional **states**. It is a non-verbal **process**

which takes place on the basis of collective **activity** as a result of a kind of mental induction. The power of excitation is proportional to the size of the audience. See R. DAWKINS "memes".

"- Imitation is the reproduction and **transmission** of **behavior models**... Imitation can be blind or conscious...

"- Conformity is a synthetic trait of a personality to be complaisant to the pressure of the **group**. If this complaisance is very strong and extends to **ideology** and morality then conformity, I believe, transforms to conformism" (1993, p. 493).

3708

VARIABILITY 1¹⁾

The individual differences between **living systems** pertaining to the same basic type.

N. BOTNARIUC states that variability "is an individual **level process**, its adequacy deriving from the very principle of **organization** and functioning of **open systems**".

Conversely: "**Adaptation** is a **population** or species **level process**... different in nature from adequacy; it is the result of the historical action of natural **selection**, which changes individual variability in **adaptation**" (1966, p.97-98).

3709

VARIABILITY 2²⁾

Temporal **variations** within a system induced by outside influences, generally **rhythmical** or **cyclical**.

This notion, introduced in this meaning by W.D. GROSSMANN and K.E.F. WATT (1992, p.8), implies a kind of consonance between the system and its **environment**.

The authors state: "... other **variations** emerge from within the system such as the heartbeat in mammals, fashions, **changes** of attitude, or **change** due to **learning** and inventions, genetic **drift** or some erratic **events**" (Ibid).

This seems a somewhat mixed bag. More or less regular **environmental variations** may evoke *characterized* variability in a system (**variations** of **metabolism**, for instance). The **limits** of this variability are fixed by the **organizational closure** of the system, combined with its **learning** capacity. Erratic **events** induce variability only if the system is equipped with the needed **variety**. If not, it would be destroyed.

F.K. BERRIEN, inspired in ASHBY's **homeostat**, expressed this as follows: "The variability of a system's **outputs** is limited by a finite number of **functions** which a given **component** may perform and a limited number of **states** which the total system may assume. The **limits**, even with a relatively simple system, are wide" (1968, p.55).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3710

VARIABLE ^{1) - 2)}

"A measurable quantity which at every instant has a definite numerical value" (W.R. ASHBY, 1960, p.14).

ASHBY states: "... every real '**machine**' embodies no less than an infinite number of variables, all but a few of which must of necessity be ignored... Faced with the infinite number of variables, the experimenter must, and of course does, select a definite number for examination – in other words, he defines an **abstracted system**...

"Because any real '**machine**' has an infinity of variables, from which different **observers** (with different aims) may reasonably make an infinity of different **selections**, there must first be given an **observer** (or experimenter); a system is then defined as any **set** of variables that he selects from those available on the real '**machine**'. It is thus a list, nominated by the **observer**, and is quite different in nature from the real '**machine**'. (Ibid, p.15-16).

As to G. PASK, he put it in this way: "Attributes of an assembly are identified with the variables in a mathematical **model** to form a system" (1961a, p.116).

Also G. KLIR states that "A variable is always an abstract (mathematical) thing. It may, or may not represent some observable or measurable attribute of the real world" (1991, p. 47).

As a consequence, systemic **models**, when formalized, are **sets** of **interconnected** variables.

As the **concept** of 'variable' implies the comparison of different values at different instants, it implies also by necessity a reflexion about the **concept** of **time**.

3711

VARIABLE (Basic) ²⁾

Any variable specific to the system and whose **changes** are relevant for the **model** to be constructed.

The **model** must also take **supporting variables** (general conditioning ones) in account.

3712

VARIABLE (Coenetic) ²⁾

A variable which is "the common causal determinant of the **state** of both the **environment disturbance** and the **situation** at the same **time**" (S. BEER, 1968, p.285).

The **concept** was created by G. SOMMERHOFF and reflects the unavoidable fact that any system is linked to a specific **environment** which may disturb it.

Thus, in many cases, the separateness of a system is partly an illusion (Ibid, p.391), and we should scrutinize its **environment** whenever an internal **disturbance** appears.

3713

VARIABLE (Command) ²⁾

"An internal variable of a system which is under the control of a **decider subsystem**" (B. WALLISER, 1977, p.129).

WALLISER distinguishes two classes of command variables:

Control variable: A command variable with continuous effect in **time**. This is practically equivalent to a **regulator**.

Decision variable: A command variable operating discontinuously in **time**. This type corresponds to more or less frequent direct interventions of the **decider**, who may for example modify the calibration of a **regulator**.

3714

VARIABLE (Critical) ²⁾

A variable that must be maintained between a specific maximum and minimum.

If this condition is not respected the result is generally the destruction of the system. Different **interconnected** critical variables may regulate reciprocally, as for example in ASHBY's **homeostat**, endowed with **ultrastability**. As expressed by St. KAUFFMAN: "Those variables must be kept in bounds by the coordinated dynamical **behavior** of the system coupled to its environment" (1993, p.524).

3715

VARIABLE (Environmental) ^{1) - 2)}

Any variable **exogenous** to the system considered, which exerts an influence on it.

Some environmental variables are easily and generally perceived. Some others remain ignored or occult.

The system's **equilibrium**, and even sometimes its **survival** may however depend on a correct **perception**, and eventual satisfactory **management** of the **responses** of the system to some critical environmental variable. Consequently their **monitoring** is important to verify that they remain within **limits** compatible with the system's needs and to decide some adaptive **action**.

3716

VARIABLE (Flow) ²⁾

A variable which controls the exchange of **matter**, **energy** or **information** between **subsystems** within the system, or between various systems within a common **environment**.

This notion has been widely used by J. FORRESTER in his **Systems dynamics**.

3717

VARIABLE (Goal-seeking) ²⁾

A variable which enhances the capacity of the system to reach a specific **goal**.

G. KLIR states: "By applying (such a) variable as an additional **input** to the **goal-implementing element**, its **performance** with respect to the **goal** increases" (1991, p.146).

KLIR also explains how a goal-seeking variable should be selected, adding that "The main difficulty in selecting a proper goal-seeking variable is that its influence upon the **goal** variables is usually not fully known" (p. 148) and must thus be previously investigated.

3718

VARIABLE (Relevant) ^{1) - 2)}

A variable whose **variations** *practically* matter for the system's **behavior**.

Sun flares do not seem to influence *notably* the timetable of railways systems. However, blizzards may do. One and the same variable can be relevant for one system and irrelevant for another one. Tides are relevant for harbours and navigation lines, but are not for bus lines (save f. ex. in case of being them connected with a ferry line).

There are also degrees of relevance: some variables do continuously condition the system's **behavior**, as for example voltage for a sawmill; some others have only incidental relevance.

A normally irrelevant variable may sometimes become crucially relevant, as for example a forest fire for the global **ecology** of a national park.

Generally, variables are considered relevant when their influence is permanent or frequent, mainly in relation to the **goals** assigned to the system.

Serious problems may however emerge when, for some reason, relevant variables remain hidden from the **observer**.

3719

VARIABLE (Sliding) ²⁾

"The **linear** combinations of some quantity and its temporal derivatives (J.J. SLOTINE, 2002, p. 19)

Such variables are widely used in **controls**. They can be selected in order "to reduce a problem at some **level** into a first order one, much easier to solve. This corresponds to the mathematical creation of series of contractant **modules**" (Ibid)

→ **Contraction**

3720

VARIABLE (State) ²⁾

"A variable which indicates the **accumulation** of some quantity in the **time** dimension".

J.de ROSNAY observe that it "thus indicate the result of an integration" in the mathematical sense (1975, p.91).

3721

VARIABLE (Supporting)²⁾

A variable of general character "within which **changes** in **states** of the basic variables occur" (G. KLIR, 1991, p.49).

"The most frequent examples of supporting variables are those representing **time**, **space**, or various **populations** of individuals at the same time" (Ibid).

3722

VARIABLES as percepts³⁾

According to W.T. POWERS et al "A variable is always a combination of two classes of **percepts**. One class contains **percepts** which do not vary: by these **percepts** we keep track of the "identity" of the variable. The other class contains **percepts** which do change: these **percepts** carry the **information** about the "magnitude" of the variable. "Magnitude" is used here in its most general sense, including the meanings of "intensity", "size", or any other word for the general class of variable attributes" (1960, p.63).

It is of course useful to be remembered about this non-mathematical origin of the concept of variable.

3723

VARIANCE²⁾

The total number of conditions which define a system and may be modified without destroying it.

Variance is closely related to **variety**, considering that the possibilities for **variation** depend on the richness of the **repertory** of the systems possible **states**.

The **limits** to variance are closely related to the nature of the system and must respect **compatibility** with its capacity for **autopoiesis** and its necessity for **dynamic stability**.

Moreover, a major potential variance implies a maximum of **autonomy** for the system.

3724

VARIANCE ANALYSIS²⁾

Any technique aiming at making **predictions** about the **behavior** of a **variable** or system on base of its former **behavior**.

The technique to be employed should correspond to the nature of the system, as for example, fully **linear** or **deterministic**, **ergodic**, or **chaotic**.

3725

VARIANCE (Co-)^{1) - 2) - 4)}

Reciprocal adjustment **process** between a systems internal **variations** and its **environment's variations**.

The degree of co-variance between the system and its **environment** depends basically upon their acquired **state** of reciprocal **adaptation**, obtained through the accumulated action of their more or less conjugated **evolution**.

Thereafter, it is always possible that unprecedented environmental **variations** should produce:

- either a new type of **adjustment** in the system,
- or its destruction.

However, co-variance also may produce inverse effects.

Life deeply modified our planet's atmosphere through the geological times and did transform the earth's crust, with the shaping of calcareous rocks by marine **organisms** or the genesis of mineral oil.

The **emergence** of some superior animals, and notably of man tends to put still more in reverse the **process** of reciprocal **adjustment**. Specially man tends to take evermore initiatives aiming at wide environmental **transformations**. However, the **environment**, in turn, is starting to "retort" more and more forcefully.

The importance of the **process** of co-variance is likewise obvious for human systems as for example enterprises, or in macro-economy problems, or in **prospective**.

3726

VARIETY^{1) - 2)}

1)"Given a set of **elements**... the number of **elements** that can be distinguished" (W.R. ASHBY, 1951, p.167).

2)"A measure of **uncertainty** or the amount of **selection** needed to remove the **uncertainty**" (G. PASK, 1960, p.116).

ASHBY explains: "Thus the **set** {gbcgbc} has a variety of 3 letters... For many purposes the variety may be more conveniently measured by the logarithm of this number. If the logarithm is taken to base 2, the unit is the **bit**. The context will make clear whether the number or its logarithm is being used as measure" (Ibid).

Generally it is now understood that the measure of variety is expressed in **bits**. Using this base, a **bit** is the quantity of **information** needed to reduce **uncertainty** by half. (thus the connection between ASHBY's and PASK's definitions).

Variety as a concept may look deceptively trivial. However, a still quite simple system, as ASHBY's **homeostat**, with 4 **elements** and 25 different possible positions for each of them offers already a variety of 25^4 , i.e. 390.625 combinations. Really **complex system's** variety overcomes our imagination and, in order to give them some definition, **constraints** become an absolute necessity.

3727

VARIETY and COMPLEXITY¹⁾

Variety, in ASHBY's sense, is the condition for **complexity**.

J.de ROSNAY explains it in the following way: "The **growth** of a **complex system** – in volume, **size**, or number of **elements** – depends on **positive feedbacks** and **storage** of **energy**. Indeed, a **positive feedback**, when always working in the same way, results in the accelerated **growth** of some specific **magnitude**. It may be the **number** (**growth** of a **population**), **diversity** (variety of the **elements** and of their **interactions**), **energy** (surplus of **energy**, profits accumulation, capital **growth**).

"The **positive feedback** is equivalent to a **random variety generator**. It enlarges the slightest difference. It increases the possibilities for **choice**; accentuates **differentiation** and generates **complexity** by multiplying **interactions** possibilities.

"Variety and **complexity** are strongly related. But variety is at the same time one of the conditions of **stability** of any system. Indeed, **homeostasis** can appear and subsist only through a very great variety of **regulations**. The more complex the system, the more complex the **control subsystem** must be, in order to match the multiple **perturbations** coming from the **environment**. This is what the *Law of Requisite Variety* (proposed by W. Ross ASHBY in 1958) expresses. This Law, extremely general, establishes in a mathematical form that a system's **regulation** is efficient only if it relies on a *control system as complex as the system itself*. In other words, **control** actions must have a variety equivalent to the variety of the system. In **ecology**, for example, it is the variety of species; the number of ecological "**niches**", the wealth of **interactions** between species and between **community** and **environment**, which guarantees the **stability** and permanence of this **community**. Variety allows for a very extended supply of **responses** to the possible forms of aggressions from the **environment**".

Variety is thus clearly correlated to **size**.

de ROSNAY still adds: "Variety generation may thus lead to **adaptations** by increasing complexity. But by confrontation with **environment's randomness**, it generates also the *unexpected*, which is the source of **change**. **Growth** is thus at the same time the prime mover of **change**, and the way to adapt to the **environment's** modifications. One glimpses the way through which a **homeostatic system** may evolve, while constructed to resist **change**. It evolves through a complementary **process** of desorganization (partial or total) and of reorganization. This happens either during the clash of the system with **random perturbations** from the **environment** (mutations, **events**, **noise**), or during the readjustment of some **desequilibrium** resulting, for example, of too fast a **growth**" (1990, p.120).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3728

VARIETY and ENTROPY¹⁾

J.L. LE MOIGNE established the noteworthy following relation between variety and entropy: "The variety V of a system is in bi-univocal correspondence with its entropy E. As entropy grows more and more, variety decreases steadily".

One could state a quite similar idea by saying that entropization leads the system from (organized) **heterogeneity** to (inorganized) **homogeneity**.

It should however be observed that this is strictly true only for the systems that remain close to the **steady state**, or for the absolutely theoretic and abstract **model** of the **isolated system**.

On the contrary, systems faraway from the **steady state**, may emerge toward a higher degree of **organization**, if they undergo giant **fluctuations**. In this case **dissipative structures** may appear and lead to a growing entropy production.

However, the bi-univocal relation pointed out by LE MOIGNE reappears when the new system reaches at its own **level** a new **steady state**.

3729

VARIETY (Distributed)^{1) - 2)}

In a **population**, the scattering of basic characters among numerous individuals.

H.G. BURGER describes this situation as follows: "Instead of **reserve** being latent, as in plasticity, it can be ready-formed, manifested in **diversity**. Each individual can then specialize and utilize all his talents without the overhead burden. Such a scheme provides multiple, variant individuals within a species. Each specimen need incorporate a **random** part of the potential range..."

"Should emergency arise, those individuals with the appropriate talents survive. The others perish" (1967, p.210).

This concept is useful in sociology and economy as well as in biology and **ecology**.

Incidentally, BURGER uses the term "**reserve**" instead of variety. His description thus links variety with the existence of **reserves**. This is a bridge between VENDRYES's concept of the **counter-aleatory** role of **reserves** and ASHBY's concept of **requisite variety**.

3730

VARIETY (Law of optimum)^{1) - 2)}

Such a law has been proposed by N. PARITSIS in the following terms:

"... for a given **organism**, **environment** and **time**, there is an optimum variety (and **information**) in the **environment**, which

a) is as low to enable the **organism** to be adapted on the basis of its **requisite variety**,

b) is as high to allow and induce **development**,

c) at the same time does not produce **overload** or **underload stress**.

"This optimum variety has also an optimum **rate** of gradual increase that results to a combination of higher and safer development and **evolution**" (1992, p.37).

It must be stressed that, as stated by PARITSIS himself, optimum variety expresses an **environment's** property in relation to a specific **organism**.

PARITSIS also observes that variety in the **environment** implies the need for adjustment **processes** in the system, as stated by J. MILLER.

3731

VARIETY (Limits to)²⁾³⁾

"The limits to the number of possible **states** of a system (1998 c, p. 56) (variety used in the sense of s-variety I identified in my earlier piece, that is, the number of states possible within a system)" (R. GLANVILLE, 1998 a)

The most general limit to variety is **BREMER-MANN'S limit**, based on this author concept of the whole matter content of the universe (hypothetized as closed, of course) "as a perfect and ideal atomic **computer**".

Starting from such a view "the world has vastly more variety than any one of us can dream of having" (1998 c, p. 62)

GLANVILLE concludes: "This means that we are left with two options. To try to control the world by reducing its variety (leading to a very restricted and normative life), or to go with it, accepting that it is beyond our **control** and enjoying the novelty it offers us through its variety" (Ibid)

These options appear in any practical **situation** or **issue**: we would ideally need to strike a convenient balance between control and **openness to creativity**.

In fact, excessive control may lead to sterility and paralysis, while insufficiently controlled creativity veers easily onto **anarchy** and **disintegration**.

→ **Bottom up; Organization; Top down**

3732

VARIETY (Maximum proper)²⁾

The variety of a system as "determined by the product of the **degrees of freedom** of each of its **subsystems**" (F. HEYLIGHEN, pers. comm.).

HEYLIGHEN comments: "In general it seems sufficient to remove certain (inadequate) **constraints** in order to increase the **variability** of the system. However it is clear that variety cannot be increased indefinitely in this way... If we want to increase (it) beyond this limit we will have to increase the number of **subsystems**, in accordance with TURCHIN's proposed mechanism (of **meta-control emergence** or building" (Ibid).

3733

VARIETY (Requisite) (Law of)

"Only variety can destroy variety" (W.R. ASHBY, 1956,, p.207)... or

"R's Capacity as a **regulator** cannot exceed its capacity as a **channel** for variety" (W. R. ASHBY, 1951, p.171).

In other words, the **efficiency** of a **regulator** in resisting **environmental disturbances** depends of the number of countervailing options it can produce.

For a system, this means that its **regulators** are able to maintain the system **organization** only to the extent that they can produce alternative **states** for any **perturbation** imposed by **environmental noise**.

Explain H. ATLAN: "This law is important... to understand the minimal conditions of **structure** needed for the **survival** of any system depending on an **environmental source** of aggressions and **random perturbations**.

"Let us consider a system exposed to a number of different possible **perturbations**. It has at its disposal a number of **responses**. Among the multiple possible **states**, only some are "acceptable" in view of the **finality** (at least apparent) of the system, which may be its sheer **survival** or the accomplishment of some **function**. The **regulation** is meant as choosing among the possible **responses**, those that will place the system in an acceptable **state**. ASHBY's law states a relation between the variety of **perturbations**, the one of **responses** and the one of acceptable **states**. Variety of **responses** must be bigger if variety of **perturbations** is big and the one of acceptable **states** small. In other words, a great variety of available **responses** is needed in order to insure a **regulation** in a system such as to maintain it in a very limited number of **states** while submitted to a great variety of aggressions. Still more, in any **environment** being a **source** of variable and unforeseeable aggressions, variety in the **structures** and **functions** of the system is an requisite factor of **autonomy**" (1972, p.25).

This celebrated law was proposed by W.R. ASHBY in 1956. R. VALLÉE comments it in the following way: "Schematically, this principle, which is still controversial, as restated by R. CONANT (1969, p.334-6), says that the ability of a **feedback** device (for example a **regulator**) to resist successfully to a perturbing **noise**, increases with its capacity to transmit a greater quantity of **information**, per **time** unit, through its **feedback** chain. We have here a concept derived from SHANNON's theory (the capacity to transmit **information**) and an idea coming from **games theory** (the ability to resist to an opponent), the variety requisite for achieving the chosen **purpose**, being the variety of **informations** transmitted per **time** unit" (1993a, p.88).

In very complex **interrelations** between a system and its **environment**, it is not possible for the system to obtain absolute **control** over its **environment** because there is an upper **limit** to the **variety** that the system may contain.

3734

VARIETY (Spatial) ²⁾

W.D. GROSSMANN and K.E.F. WATT (1992) introduce the notion of spatial variety which refers to the spatial differentiation within systems, as different from their possible temporal **variations**, related to ASHBY's **variety**, and which they call **variability**.

Spatial variety is defined by a more or less high degree of fineness in spatial differentiation, or, to the contrary to its coarseness. They use the term "grain" in this meaning. The notion is applicable for instance to **ecosystems** or to human **organizations**.

3735

VARIETY (Structural) ²⁾

The **set** of connected **structures** in a system.

3736

VARIETY ENGINEERING ⁴⁾

The practical ways to make **controls** efficient in **human systems**.

S. BEER, who introduced the concept, states that "The manager is a variety engineer" (1979, p.39).

Variety engineering uses two complementary techniques: either reducing the impact of the **environmental** variety, or enhancing the variety of the system itself.

So-called **cyberfilters** (p.499-509) can be used to reduce the **environmental** variety admitted by the system, while internal variety can be increased. Both **processes** should be applied at the different **levels** in the system: In **subsystems** in response to **disturbances** emerging from specific systems in the environment; and in the system as a **whole** connected to the general **environment** (R. ESPEJO, 1977).

The human aspects of variety (**values**, **norms**, attitudes, etc...) represent however a mined field for variety engineering.

3737

VARIETY GENERATOR ²⁾

A device which is capable of proliferating variety.

As stated by St. BEER such a device is: "... not necessarily a machine made of ironmongery". He adds that it may be "... deliberately organized to generate (variety) for a **purpose**. ... the **purpose** is not known in advance, although of course the *kind* of **purpose** is known" (1968, p.297).

A grid on a **map** is a good example: it differentiates **locations**, or at least permits their differentiation when needed. Any variety generator creates opportunities for **selection** within a wider pool of possibilities.

3738

VARIETY RATE ²⁾

"The variety that a system is able to show during a given interval of **time**" (J.L. LE MOIGNE, 1977, p.167).

This quite significant complement to the concept of variety was introduced by VAN COURT HARE (quoted by LE MOIGNE).

Of course, most systems are only able at a given moment to use a reduced part of their total variety. Thus, even if they count, in principle, with the **requisite variety**, it does not follow from this that they will be able to use it.

This potential problem seems quite serious for **complex systems** of very wide dimensions, doubtless partly due to the length of their **communications** lines.

3739

VARIETY REDUCTION ^{1) - 2)}

The **process** of **simplification** of a system's model by **aggregation** of *similar elements* or **interrelations** and the elimination of *irrelevant* ones.

Statistical **methods** based on the use of the **law of great numbers** are a very general technique for variety reduction.

No **model** can ever be complete, i.e. **isomorphic** to the **situation** or system. On the contrary, it must be enormously simplified if it is to be manageable and useful. Variety reduction is however a tricky proposition: "**similarity**" or "**relevance**" are based on more or less subjective **criteria**, whose use may be difficult, particularly in borderline cases.

An historic example is given by the multiple – and sometimes, quite divergent – criticism directed at the Club of Rome's **World models**.

Variety reduction is also linked to the **resolution level** sought in relation to the type of **situation** to be studied.

In a different meaning, variety reduction must at times be applied to **human organizations** or **systems** wherein an excessive proliferation of **elements**, or **subsystems**, or redundant products is observed. This is a fundamental issue in controlling bureaucracies.

3740

VARIETY REDUCTOR (Perception as) ^{1) - 3)}

Any perceptor acts as a selective filter. This is true about physiological **perception**: our detection of electromagnetic waves is strongly limited. It is also true about psychological **percep-**

tion: we suppress much of our potential capacity of **perception** by focusing on specific and chosen items or topics.

→ **Perception (selective)**, **Perceptive filter**

3741

VARIETY REDUCTOR (Statistical inquiries as) ²⁾

A statistical sampling can be used as a variety reductor since it *reduces redundant information* contained in thousands or millions of **data** into a shortened synthesis which, provide correct use of statistical **methodology**, contains nearly all the **information** in a practically usable form.

A good example is the use of demographic statistics by life insurance companies and, more generally, any statistical inquiry used by any company or public administration board to understand its **environment** and take relevant **decisions**.

3742

VECTOR ²⁾

"An ordered **set** of numbers that specify the values of **variables**" (G. PASK, 1961a, p.116).

A vector completely specify a quantity and a direction.

3743

VENN DIAGRAM ²⁾

A two-dimensional graphical **representation** of the intersections of different **sets**.

The **representation** is based on intersecting closed curves representing the various areas corresponding for example to a, non-b, non-c; a, b, non-c; a, b, c; ... non-a, b, c; etc...

However, the great difficulty was to represent the intersections of more than 3 **sets**. This problem has now been solved by A. EDWARDS of the Gonville and Caius College of Cambridge University, England (1989, p.51-6). EDWARDS uses "toothed" curves, by means of which he obtains a kind of **fractalization algorithm** that allows for the highly symmetrical **representation** of the intersections of any number of **sets**. These VENN-EDWARDS diagrams are a great help for visualizing complex **interrelations** between many systems.

Multidimensional and multi-layered Venn diagrams are now used to classify complex and overlapping statistical **data**.

Patrick BALL, deputy director of the Science and Human Rights Program of the AAAS is using this kind of diagrams to order the multiple data about different types of violations of human rights by different people or groups in many places and times (W. GROSSMANN, 2003, p. 48-51)

This method is useful to control **reliability** of testimonies and obtain an **evaluation** of the **density of reporting** in specific cases.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3744

VIABILITY¹⁾

The condition of a system able to survive after birth, to **grow** and to reach enduring **dynamic stability**.

This is, generally speaking, the condition of **autopoietic** and **autonomous systems**.

W.D. GROSSMANN and K.E.F. WATT understand viability as "temporal **variety**" and discuss this notion as follows: "To be viable, systems must have manifold features that will allow them to withstand the impact of expected as well as unforeseen and erratic **events**. It would be desirable to have systems that could even benefit from the unexpected" (1992, p.5).

The authors state that viability transcends C.S. HOLLING's idea of **resilience**, because it "... includes the notion of coming into existence and ultimately **disintegrating**" (Ibid).

According to them: "... **diversity** may in some cases contribute to viability" (Ibid).

This is acceptable if **diversity** is **variety** in ASHBY's meaning, or systemic internal **heterogeneity**, when various **functions** or **groups** can contribute numerous and varied **adaptations**.

As **diversity** is commonly antagonized by uniformization (as in chain production, for instance), or autocratic and limiting **control**, so could be viability. However, **diversity** should necessarily remain within the limits of **organizational closure**, to allow for **coherence** in the system.

According to E.von GLASERSFELD viability has its meaning in the cognitive domain: "Briefly stated, concepts, theories, and **cognitive structures** in general, are viable and survive as long as they serve the purposes to which they are put, as long as they more or less reliably get us what we want" (1988, p.138).

Such a view is closely related to POPPER's "falsification" and KUHN's shifts of **paradigms**.

From a similar viewpoint, Systemics will be viable only if it will produce practical **responses** to complex **issues** that former **methodologies** and theories cannot give.

3745

VIABILITY DOMAIN²⁾⁴⁾⁵⁾

The limits wherein a system must remain in order to insure its **survival**.

The concept is clear in Biology. Any system that starts with some lethal gene will not survive very long time.

Moreover if it produces some offspring, these will be at an evolutive disadvantage in relation with more favorably endowed beings.

On the contrary, a **mutation** may enhance the **survival** potential of the system by expanding the **environment** in which it will be able to survive.

In social systems however it is much more difficult to evaluate how their viability can be affected and in which **limits** by some extrinsic or intrinsic condition or **event**.

→ **Artificial life**

3746

VICINITY²⁾

Proximity in space.

In **topology**, the vicinity of two points is defined by their common membership in a **set** or in a **basin**.

Vicinity is a near synonym for **neighborhood**.

3747

VIEW¹⁾²⁾⁴⁾

A projection of a complete **model** of some **situation** or system composed from different partial perspectives (or views) on to a particular **subject**.

J. LIND (2000, p. 640-1), who proposes this...view, distinguishes:

- the **task** view through which a task **hierarchy** is generated to determine the basic **problem solving** capacity or possibilities available
- the **environment** view which considers the nature of the **relationship** of the system with its environment
- the **role** view which "determines the functional **constraints** that characterize the capabilities of the different active **agents**"
- the **interaction** view which considers how the needed **communications** among active agents must be ordered in function of the pursued **goals**
- the society view seeks a model consistent with the **roles** as they are accepted and interconnected within the society
- the architectural view "is a projection of the general **organization** needed to manage a specific **situation**. It includes for ex. "**agent management** or database **integration**"
- "the system view which seeks a kind of final coordination dealing "with aspects that affect several of the other views at the same time or even the system as a **whole** (loosely summarized from A. LIND's paper, who aims at practical management uses)

→ **Design; Design (Generic); etc...-Management; Multi-agents system**

3748

VIEWPOINT^{1) - 3)}

The peculiar angle under which an **observer** focuses his or her attention on a complex **situation** or system.

R. ESPEJO stresses that "**Complexity**, as opposed to **variety**, is something that results from the **interaction** of the viewpoint with the **situation**. **Complexity** is in the eye of the beholder" (1988, p. 140).

Variety itself, is intrinsic and, save in very simple theoretical examples, never completely observable, because it becomes readily gigantic. St. BEER observed that 7 **elements** could have 2⁴² possible **patterns** of **interaction** in time.

Much reduced descriptive **models** of **complexity** are extracted from potential or real **variety** by specific ways of observing systems. Moreover, **descriptions** by different **observers** may not coincide ... and generally do not.

Even the same **observer** may very well describe a system or **situation** in different ways, according to his or her interest at the moment.

Moreover, any personal **description** is generally biased, even unknowingly, by the **observer**.

Better **descriptions** are in principle made by **groups** of **observers** from different viewpoints, and still more so if they use reasoned **criteria** and seek **consensus**.

It should also be taken in account that personal or shared viewpoints do not remain permanent in **time**, being influenced by **learning**, experience, debate, etc...

Stressing the importance of viewpoints will help systemists to avoid becoming doctrinaires liable to theoretical abuse.

→ **Weltanschauung**

3749

VITALISM^{1) - 3) - 5)}

"The theory that life is maintained by some special force that cannot be explained by the principles of physics and chemistry" (J.Z. YOUNG, 1974, p.300).

As noted by YOUNG, this theory was closely related to DRIESCH's **entelechy**.

It was a purely verbalist pseudo-explanation, but it had the merit to consider living beings specificity and to trigger a controversy which led in a first step to BERTALANFFY and WOODGER's **organicism**, and from there to the concept of system, which emphasized the importance of internal **interrelations** and **organization**.

Later on, MATURANA and VARELA's **organizational closure**, and EIGEN's **Hypercycle** introduced a clearer explanation for the **maintenance** of **organization** in living systems. On the other hand, PRIGOGINE showed that a correct extension of **thermodynamics** to **open systems**, especially those faraway from **equilibrium**, could constitute a physical explanation of the **evolution** of life.

3750

VOLITION³⁾

"Conscious **purposeful behavior**" (M. BUNGE, 1979, p.172).

BUNGE enounces a systemic viewpoint about volition: "The will is not an entity but a **neural activity**... Nor is the will a mysterious faculty of an immaterial **mind**, but a capacity of highly evolved Central Nervous Systems, namely a control of **behavior** by the thought **process**" (1979, p.173).

Of course, BUNGE considers thought itself as an **activity** of the Central Nervous System.

It is interesting to compare these views with P. VENDRYES' and on the other hand H. MATURANA and F. VARELA's concepts of **autonomy**.

3751

VOLUTION ²⁾

A turn or twist about a center or a spiral, within a **whirl** or a **vortex**.

This is a characteristic feature of **toroids**, as a general systemic **model** proposed by D. Mc NEIL (1993,a,b), who writes: "The combined effect of systemic **order** and repeatability is to produce a **loop** or **cycle** of an ordering, i.e. a **voluntary organization**" (1993 b, p.5).

Still more generally, a volution is the materialized expression of **energy transfers** in a **field**.

3752

VON NEUMANN ARCHITECTURE ²⁾

The **set** of basic concepts for sequential **data** processing.

Practically all **data** processing machines are still based on the following principles, proposed initially by J.von NEUMANN:

- a central processing unit
- a store of **data** that must be at the disposal of the central processing unit
- a **set** of instructions (or **program**) that can be applied to **data** in order to obtain certain predefined results, within the limits of the **content** of the **program**.

This is a purely **algorithmic** concept: The machine is enabled to do anything that is programmed, within the limits of the existing **data**, but cannot do anything else. In particular, it cannot **learn** anything.

The new **connection machines**, based on **parallel distributed processing** through small individual units, on the contrary, may learn by using **rules**.

3753

VORTEX ^{1) - 2)}

A **flow** rotating about an axis within some **medium** which acts as an **environment**.

Vortices may appear in the most different types of fluids: stars clustered in spiral galaxies, planetary atmospheres (cyclones, hurricanes, typhons), oceanic waters, glaciers, rivers, vegetal and animal tissues, etc...

The French engineer Ch. LAVILLE devoted a book to vortices and wrote: "Whirling **flows** are **trajectories** along lines of least resistance. This implies that they condition the duration possibilities of a **phenomenon**".

"Vortices appear as **phenomena** limited in **time** and **space**: they arise, they grow, they go through a period of **dynamic stability**, they decline and disappear". Even so, they may frequently remain **dynamically stable** for a long duration.

"The **emergence** of a vortex is submitted to two conditions: an adequate **environment**, fluid by necessity (gaseous, liquid or finely divided solid) and a certain **heterogeneity** in this **environment**. In fact, all vortices arise from a movement of tangential opposition upon a mass in **translation**, thus creating a gyratory movement. Vortices thus result of the conjugated action of the central force that produced the **translation** and a couple creating the gyration; in other words, *they are determined by a dissymmetry* and, in their initial **phase**, they appear as a coil in the fluid mass"...

"The composition of both movements, **translation** and gyration, that characterizes the vortex, produces closed helicoidal lines developing around a central axis, thus materializing brachystochrone (i.e. of shortest duration in time) **trajectories**"...

"The vortex, in synthesis becomes individualized within the amorphous mass, of which it separated to take its **form**. To reach to this shape, it conforms to the following condition: The **structural set** of its current or tension lines communicates its resistance to oppose its deformation or destructure by the **environment**" (1950, p.52-54).

These characteristics clearly show that all complex systems are in a sense stationary vortices of structuring **energy**.

The vortex model is quite important for the understanding of the genesis of systems. It relates to the following complex phenomena:

- the basic **symmetry-breakings**
- the resulting **instabilities of energy flows**
- the **energy-matter** equivalence
- the **process-structure interrelations**
- the genesis and **transformation of forms**

See for instance d'ARCY WENTWORTH THOMPSON book "On growth and form" (1916).

LAVILLE made moreover these interesting comments:

- Vortices are minimum resistance **trajectories** and, consequently condition the possibility of duration of a **phenomenon**.
- Vortices as **phenomena** are limited in **space** and **time**: they arise, grow, attain **dynamic stability** for some time, until they decline and disappear.
- A vortex separates from its **environment** and acquires an **identity**

- As its **field** communicates it a resistance to external **disturbance**, it becomes a more or less durable **organization**. (Ibid)

This last point offers an interesting insight into the very basic and general nature of **auto-poiesis** and **organizational closure models**.

→ **Fields (Interaction between)**

3754

VORTEX (Stationary) ²⁾

A **vortex** which maintains unchanged its rotation rate (R. ROBERT & J. SOMMERIA, 1992, p.947).

This is the state of **dynamic equilibrium** of a **self-reproducing** vortex within a sufficiently stable **environment**.

The **analogy** with the concept of **organizational closure** seems obvious.

3755

VORTEX (Sub-dividing) ^{1) - 2)}

Ch. LAVILLE observed that any vortex may, under specific conditions, generate smaller vortices. He writes: "We may witness either a conjunction of separate vortices into a unique one, or the disjunction of one vortex into various individual ones" (1950, p.55).

As to the subdivision **process** he states: "The volume of a vortex does not seem to be able to exceed a certain **limit** depending on the conditions of its formation. Over this **threshold** it maintains the **coherence** needed for its **survival** by fractioning into smaller vortices" (Ibid)

Each of these corresponds to a **limit cycle**.

This **process** of production of vortices within vortices, etc... seems to be a very important factor of internal diversification, closely related to the construction of **complex systems** through subdivision and qualitative **differentiation of channels of energy flows**.

It would be interesting to try to connect the study of subdividing vortices with **fractals** theory and **deterministic chaos**.

→ **See also: Fields within fields**

In some cases, small vortices also can combine and construct a greater one at a higher **level of integration**, as shown by A.P. INGERSOLL's models of Jovian vortices (quoted by J. BRIGGS and F.D. PEAT, 1991, p.125).

3756

VORTICITY ²⁾

The local rotation **rate** in a whirling **flow** or **vortex** (R. ROBERT & J. SOMMERIA, 1992, p.947).

3757

VORTICITY CURVE (Iso-) ²⁾

"A curve which delimits a **zone** of equal rotation in a **vortex**" (R. ROBERT & J. SOMMERIA, 1992, p.947).

W

3758

WARNING (Early)¹⁾

Any **symptom** of probable **change** that can only be observed and understood within a systemic **framework**

Early warnings offer some **predictability** in **nonlinear systems**, even if within **limits**.

Predictability in **linear processes** is theoretically reliable. However, **linear processes** are exceptional and generally quite **unstable** in **time**.

Nonlinear systems are submitted to different **short, median and long term trends**, which are imbricated and mutually **constraining**. **Long term trends** are difficult to discover, because the needed **data** must cover a **span** that easily exceeds the professional life of a scientist, or manager, and even the accumulated historical **information**. Examples are **long term** reversals in stock markets; the movement of geological faults; multisecular mega-floods in river basins, etc.

However, **long term trends**, once established, constitute a more or less reliable frame for **median and short term oscillations**. This means that any strong or sudden **deviation** in these lesser **trends** probably heralds a reversal of the **phenomenon**, or **behavior** of the system, possibly in a **catastrophic** or **chaotic** way.

The development of a good general theory of early warnings could become a very significant contribution of systemics.

3759

WASTE^{1) - 4)}

Any unnecessary, useless, or nocive **output** of a system.

There are many different types of wastes. However most kinds can be classified as a useless **output** of either **matter**, or **energy** or **information**.

The sore point in the definition is the "useless" adjective. In many cases, it really means that we do not *see* any use for that specific **output**. In natural systems however, every **output** is finally recycled and again transformed into a **resource**, with the exception of *final residual heat*.

As to now, organic waste is generally recycled through biodegradation (but this process may take a long time and excesses of organic waste may asphyxiate some **ecosystems**). Inorganic waste, generally of artificial industrial and domestic origin, is mostly non-degradable, at least for an indefinitely long period, and tends thus to have these suffocating **side-effects**.

Many artificial wastes, produced by human systems, could possibly be recycled (and should be, whenever "practically" – another doubtful adjective – feasible).

A good general **understanding** of the various kinds of waste **flows** and their actual as well as possible alternative **circuits**, is the first step toward this end.

H.T. ODUM writes: "The cheapest way would be to use man's waste **flows** to stimulate the **circuits** of his interest" (1971, p.290).

He adds that, when various possibilities of recycling do exist, value decisions should be based on the most efficient use of **energy** (in **thermodynamic** terms).

Unfortunately, this still remain mostly wishful thinking because, in the words of E.J. KROWITZ: "How to measure **entropy** content; how to model the economic **transformation** in **entropy** terms, and measuring the environmental-**resource limits** all pose major obstacles to implement the concept" (1991, p.45).

3760

WAVE^{1) - 2)}**A periodic oscillation.**

There are many classes of waves. A. BOGDANOV considers waves as "... the most widespread method in nature of preserving or restoring **equilibria**". Moreover "This is a kind of general **model** for innumerable **processes** of the inorganic universe... But this **model** is also applicable without limit to the realm of life: almost all of the life **processes** are of the **periodic oscillation** type" (1980, p.9).

However, even in this sense, waves seem to ride on more generic **long term trends**. E. JANTSCH, for instance, writes about "waves of **organization** (which) may be understood as another manifestation, at a **macrolevel**, of the basic evolutionary mechanism of "**order through fluctuations**", of a **rhythm** alternating between **stabilization** and **mutation**, as it has been described for **nonequilibrium** physical systems". (1975, p.253).

N. ELDEREDGE and S. GOULD's model of punctuated (i.e. by periodic waves) **evolution** looks like another example of waves riding a more fundamental **trend** (1972, p.82-115).

3761

WAVE and TIDE MODEL¹⁾

A metaphoric **model** of the superposition of shorter and longer **cyclical oscillations**.

This **metaphor** was introduced by E. HERRSCHER (1989) and is quite useful for transmitting the understanding of the **interrelations** and interferences between **oscillations** of different **periods** and **amplitude**.

3762

WAVE Cycle (Long)

→ Cycle

3763

WAVE (Stationary)²⁾

A stable **periodic** regime of **oscillations**.

Various collaborators of PRIGOGINE, members of the so-called Brussels School, experimenting with chemical systems (for example the **BELOUSOV – ZHABOTINSKY** reaction: the oxydation of malonic acid by potassium bromate, in presence of cerium ions), discovered "... The existence of a stable **periodic regime** which corresponds to the alternation of a rapid **phase** of chemical waves propagating toward the center and a slow **phase** tending to homogenize the system" (G. NICOLIS & I. PRIGOGINE, 1977, p.100).

Stationary waves are closely related to **dissipative structuration**. They maintain themselves as long as the system remains **nonlinear**.

It would be quite interesting to research stationary waves in biological and **social systems**
→ **Soliton**

3764

WAVES (ELLIOTT'S)→ **ELLIOTT'S waves**

3765

WEAR¹⁾

The gradual impairment of a device or system.

Wear is a universal **phenomenon** in natural as well as in artificial systems, obviously connected with **entropy's** increase. P. WINIWARTER and C. CEMPEL, who investigated wear, define the following aspects of the wear problem:

- Wear leads timely to the destruction of the system. In natural system "wear causes death". In artificial ones, it leads to **break-down**.
- "Wear amplifies wear, a **positive feedback** leading to **autocatalytic** or **nonlinear behavior**".
- It is possible to define the notion of **break-down time**, which "is determined by the internal **structure** of the system and the way of **energy dissipation** inside the system".
- Systems have a "**life curve**", reflecting the wear **process**. It can be more or less defined and used for "**diagnosis** and **prognosis**" (1992, p.23-26).

3766

WEB¹⁾

Practically a synonym for **network**.

3767

WEBS (Multilevel)²⁾³⁾

"A class of systems in which various forces or **subsystems** interact **simultaneously** within and across **levels**". (C. HARDY, 2001, p. 35)

HARDY adds: "Webs thus exhibit dynamical **evolution** through the **cooperation** and **co-evolution of processes**" and...

"In multilevel webs, the **variety** and **complexity** of forces interacting simultaneously instantiate inter-influences between connected **elements/processes**, so complex that they render **causality** irrelevant as a **formalism**. Webs inter-influences are fundamentally **non deterministic**, and they reach beyond **causal mechanisms**".

"However, simpler mechanisms such as **linear cause-effects** and **circular causality** may exist as component processes, enmeshed in the ensemble of **interactions** of the more complex system"(Ibid.)

The crux of the matter is the **simultaneous** character of different **events** and **actions** at various **locations** in the system. As their **propagation** is generally neither **isochronous**, nor takes place in an **isotropic space**, rigorous **determinism** is impaired and replaced by statistical or **chaotic determinism**. It is however not suppressed, specially at **macroscopic scale**.

3768

WELTANSCHAUUNG^{1) - 3)}

A global paradigmatic **worldview**.

As observed by J. SUTHERLAND, any Weltanschauung "can not only serve as a guide for empirical efforts but (also) as a **perceptual filter** which can exclude **data** and causal **inferences** which would be incompatible within the context of the **paradigm** itself" (1973, p.121).

His/her Weltanschauung is the most global cultural **frame of reference** for the **observer**, who uses it and lives within it, many times without being conscious of it.

SUTHERLAND's comment actually refers to the **mechanistic** worldview, but it can be applied to *any* Weltanschauung, including of course the systemic-cybernetic one. Systemists should thus beware of conceptual absolutism and intolerance.

(Note: WELTANSCHAUUNG is a German word quite often used by some systemists, which is the reason for its inclusion in this encyclopedia).

Within the "archeology" of the concept, W.von HUMBOLDT's "Weltansicht"(World perspective) should be mentioned ("Gesammelte Schriften", Berlin Akademie, 1836-39)

3769

WELTANSCHAUUNG (Systems)¹⁾²⁾³⁾

As leit-motiv for the celebration of the 100th anniversary of Karl Ludwig von BERTALANFFY, Prof. ELOHIM (Technical University, Vienna) reproduced the following texts of this founder of the systems movement:

"The overall fate of the world depends on the adoption by humanity of a new **set of values**, based on a general systems Weltanschauung (worldview), and ...

(We must seek)" another basic outlook: the world as **organization**, (which) would profoundly change the **categories** of our thinking and influence our practical attitudes, as we must envision the **biosphere** as a **whole**- with mutually reinforcing or mutually destructive **interdependencies**"

In his introductory manifest for the celebration meeting at the Vienna Technological University- which took place in 2001- Prof. Elohim collected supporting or coincident opinions and views to BERTALANFFY's ones. Among these are notes and papers by Janet M. EATON, C.H. WADDINGTON, L. MUMFORD, R. HUTCHINGS, L. EISELEY, N. COUSINS and A. EINSTEIN.

(Personal communication from Prof. Elohim)

3770

WHITE BOX²⁾

"A system of known **components**, put together in a certain fashion so as to affect a given **input-output** functioning" (I. BLAUBERG & al, 1977, p.163).

In other words, it is any constructed **algorhythmic** device.

Consequently, the internal **mechanism** of a white box is apparent and understandable. Of course, this can be so for some **observers** and not for others, as distinct observers may produce different **descriptions** of the box, all of these mere results of their peculiar **position** as observers (R. GLANVILLE, 1979, p.35-7)

A simplistic observer may also see a **black box** as white, due to some superficial or **reductionist** way of observing. This can be very dangerous.

A possible example of this kind of simplifications is the dubious assimilation by some behavioral psychologists of man's **behavior** to a set of simple **input-output effects**. This can moreover easily lead to psychological manipulation, of the brain washing type.

Most man-made **machines** are, or at least, are intended to be white boxes. However, it frequently happens that the **components** and the way they are put together have unknown properties, which are not perceived at the time of assembly... and turn the white box into a **black box**.

3771

WHOLE^{1) - 2) - 3)}

A complete entity or system whose **components** or **elements** remain connected in a specific and globally functional way.

Wholes are no mere unstructured **aggregates**, devoid of any functionality. The basic regulating principle of coherent wholes is that every **behavior** of a **part** may influence (di-

rectly or indirectly) any other **part**. However, after a **time**, that can be very long, the global **process** may reproduce the **initial conditions**, or at least conditions very similar or equivalent.

In a whole, the **components** or **parts** become **immersed**, which means that some of their specific properties remain hidden, or become altered due to **interactions** with other **components** or **parts**. Good examples are the properties of hydrogen and oxygen atoms in water... or of a husband or father acting as an engineer in an enterprise, or vice-versa.

In G.S.T. the word "**holon**" (whose Greek origin is the same), proposed by J. SMUTS (1925, reprinted 1973), has been recovered by A. KOESTLER (1969) and is now quite incorporated within the systemic vocabulary, not however being uncontroversially admitted by all systemists. As the term "**Holon**" has been sometimes used in a careless way, "whole" is possibly a convenient substitute.

The concept of "whole" is also connected with the "**Gestalt**" one, basically in relation to our way of observing and perceiving.

3772

WHOLE and PARTS^{1) - 2) - 3)}

These antithetic concepts are very basic for the understanding of the systemic view of the world.

I. BLAUBERG, V. SADOVSKY and E. YUDIN, who consider both concepts as **categories**, write:

"The cleavage and opposition of the part and the whole produced the antinomies of **wholeness**. The principal ones were:

- 1. Thesis: the whole is the sum of parts Antithesis: the whole is greater than the sum of its parts (note: or less or other!)
- 2. The parts precede the whole. The whole precedes the parts
- 3. The whole is casually determined by its parts.

The **wholeness** approach is opposed to the causal one and rules it out

- 4. The whole is cognized through the **knowledge** of its parts

Parts as a product of division of the whole may be cognized only on the basis of the **knowledge** of the whole" (1977, p.99-100).

This traditional viewpoint has now been reformulated in a non contradictory way as stated by the same authors: "The solution of the problem lies in that **wholeness** is characterized by new qualities and properties not inherent in the parts but appearing from their **interaction** in a certain system of **connections**...

"... in the relation between the parts and the whole neither side can be considered without the other: a part outside the whole is not a part but quite a different **object**, since in an integral system the parts express the nature of the whole and acquire properties specific to it; on the other hand, the whole without (or before)

the parts is unthinkable, since an absolutely simple, structureless and even mentally indivisible body cannot have any properties or interact with other bodies" (1977, p.100).

Synthetically, a part (or **element**) within a whole (or system) is itself *plus* its **connections** with other parts and *less* the **constraints** which result from these **connections**.

As in many other cases, the old, absolute **di-chotomies** appear now as unduly simplified **abstractions**.

3773

WHOLE and PARTS relationship ¹⁾

W.R. ASHBY has established the following principle "That a whole dynamic system should be in **equilibrium** at a particular **state**, it is necessary and sufficient that each part should be in **equilibrium** at that **state**, in the conditions given to it by the other parts."

ASHBY comments: "Clearly, at any **state** of the whole, if a single part is not at **equilibrium** (even though the remainder are), this part will change, will provide new conditions for the other parts, will thus start them moving again, and will thus prevent that **state** from being one of **equilibrium** for the whole. As **equilibrium** of the whole requires that all the parts be in **equilibrium**, we can say (metaphorically) that every part has a power of veto over the states of **equilibrium** of the whole" (1960, p.79).

To take care of this aspect, R.L. ACKOFF proposes what could be called the architectural view: Essentially, no part can be changed (modified, increased, decreased, suppressed) without considering the impact of the **change** on the other parts and, if needed redesigning the whole (1995, p. 44).

While some **changes** of the parts may originate in **changes** of external **parameters** to the system, in this case this is left outside the picture.

From a new and significant viewpoint, wholes are now frequently considered **holo-graphic**. This implies that the whole is somehow reflected in every part. J.C. LUGAN offers curious insights in this sense: "Individual actors constitute society, but society, through the **socialization process**, is in each individual. Moreover, while society is produced by the **interactions** among its individuals, it retroacts by producing individuals through **education** and **language**" (1993, p.112).

In other words society tends to become **autopoietic**, by way of the scattering of its global characteristics among numerous individuals, just as if being an enormous **hologram**.

3774

WHOLE or SYSTEM or GESTALT ? ¹⁾

A. ANGVAL tried (in 1941!) to clarify in the following way the **meaning** of the word "whole": "The term "whole" is frequently used with a

very confusing double meaning. Sometimes the concrete organized **object**, other times the **organization** of the object is called a whole. The term is used in this latter connotation, for instance, when one states that a circle may be small or large, drawn in red or green color, and still remain the same whole, the same **Gestalt**. I propose that the term "whole" be reserved to designate the concrete **organized object** itself. The way of arrangement of **parts**, should be called system" (in F.E. EMERY, 1969, p.28).

After more than fifty years, the matter is not yet settled. Many authors *seem* to speak of "**concrete systems**", but J.L.LE MOIGNE considers that the system is a **model**.

In any case, it is of paramount importance never to confuse real **objects** (i.e., as we are able to perceive them), with conceptual **abstractions**.

3775

WHOLENESS ¹⁾

I. BLAUBERG, V. SADOVSKY and E. YUDIN describe the basic features of a system as a whole in the following way:

"1) The system is an integral complex of interconnected **elements**;

"2) it forms a special unity with the **environment** (in some problems the system cannot be considered in isolation from the **environment**, although this does not mean that all... problems of system and structural research are of this nature);

"3) usually any investigated system is an **element** of a higher-order system (that is, it may, in other problems, appear as a **subsystem** or **element** of a broader system);

"4) **elements** of any investigated system in their turn usually appear (again in special problems) as systems of a lower order" (1977, p.127).

The authors emphasize that "one must pay special attention to the **hierarchical** character of the system intimately connected with its wholeness. The **hierarchy** is manifested both in the chain of systems' inclusions into one another and in the **interaction** of individual **sub-systems**, including the character of the functioning of **goal-directed subsystems** and their impact upon the system concerned" (Ibid, p.127)

Thus the wholeness of the system implies the existence of **hierarchical** as well as **non-hierarchical** links.

Another aspect of wholeness is that "a variation of any **element** affects all other **elements** of the system and brings about a variation in the whole system, and vice-versa, variations of any **element** depend upon all other **elements** of the system" (Ibid, p.54).

The concept "expresses the **requeriment** for a special **description** of the system as a whole, different of that of its **elements** (non-additivity of the system as the sum of its **elements**) and

also the **intention** to oppose the system to its surroundings (the **environment**), the system's inner **activity** forming the base of the opposition" (Ibid, p.140).

J.A. GOGUEN and F.J. VARELA add some other interesting **viewpoints** about wholeness: "... it co-occurs with interesting **emergent** properties at some **level**. A sequence of notes is whole if it is an interesting melody. Similarly, the significant differences in **behavior** of cells and **organisms** from the **behavior** of atoms and molecules, marks the cells and **organisms** as whole systems".

"Another point of view toward wholeness, is that it can be measured by the **difficulty of reduction**: Because it is very hard to reduce the **behavior** of **organisms** to the **behaviors** of molecules, we may say that **organisms** are whole systems".

"A third point of view is that a system is whole to the extent that its **parts** are tightly **interconnected**, that is, to the degree that it is difficult to find a relatively independent **sub-system**".

"A fourth point of view is that a system seems more whole if it is more **complex**, that is more difficult to reduce to **descriptions** as **interconnections** of lower **level components**" (1979, p.41).

E. SCHWARZ observes that the need for making **distinctions**, which cannot be avoided, has on the other hand the negative effect, in classical scientific thought, to cut and even make disappear from our view, numerous significant **interrelations** among the **elements** and among the forces that dynamizes the **processes** (1999, p. 138-9)

This trend obviously started with DESCARTES "Discours de la Méthode"(1637)

→ **Distinction; Method (Discourse on the); Separability**

3776

WHOLENESS APPROACH ³⁾

I. BLAUBERG et al. also state that the requirements of the wholeness approach are "only seemingly simple to fulfil. In reality any complex problem must necessarily be decomposed into a **set** of subproblems each of which requires a special approach and, in particular, has an optimal solution all of its own. The point is, however, that *the optimal solution of the problem as a whole is not necessarily equal to the sum of the optimal solutions to its parts.*"

"... In other words, the entire intricate **hierarchy** of **operations** aimed at solving a complex problem must be organized in such a way that the chief and decisive **criterion** at all **levels** was a **unified evaluation** of effectivity, i.e. that the system as a **whole** and its ultimate effect should always be borne in mind" (1977, p.263).

The wholeness approach implies "the *fundamental irreducibility* of its properties to the sum of the properties of its **elements**, and the *non-deductibility* from the latter of the properties of the **whole**" (Ibid, p.269).

3777

WHOLENESS (The Paradox of)^{1) - 3)}

According to I. BLAUBERG, V. SADOVSKY and E. YUDIN: "It is impossible to cognize a system as a wholeness without "looking inside the system", i.e., without analyzing its **parts**" (1977, p.272).

Of course, the way we look inside the system is of capital significance. Instead of severing the internal **connections** between **subsystems** into **elements**, we use them as guidelines in our way of decomposing the system and never loose from sight the specific systemic **roles** of the **subsystems** and **elements**.

This is one of the basic tenets whose observance corresponds to the inverse **process**, i.e., reconstitution, which is the aim of **reconstructability analysis**.

3778

WHOLES (A logic of)^{2) - 3)}

In 1941, A. ANGYAL proposed a logic of wholes, as opposed to the logic of **relations** (but still complementary to it). He emphasized the inadequacy of the traditional logical tools for the study of complex **objects**, to which he already gave the name of "systems". He wrote, in particular: "A **relation** requires two, and only two members (relata) between which the **relation** is established. A complex **relation** can be analysed into pairs of relata, while the system cannot be thus analysed. A system may involve an unspecified number of members. A system is not a complex **relation**" (in F.E. EMERY, 1969, p.18).

He added however that there are "complex **connections** which are reducible to two-term **relations** on the one hand, and complex **connections** which cannot be (*thus*) reduced... on the other hand" and stated further on that "the type of **connections** in a whole is very different from the **connections** which exist in an **aggregate**" (Ibid, p.20).

ANGYAL expressly reserved the term "system" for "**holistic organization**"

ANGYAL views are reminiscent of RUSSELL and WHITEHEAD's **theory of types**. It is clear that the whole cannot be reduced to the "element" type, and that its relation to each element is of a different type, i.e. hierarchical (or "vertical") in opposition to "horizontal"

3779

WHOLES as Parts, parts as WHOLES^{1) - 2)}

Any system is part of the **environment** in which it is inserted and this **environment** is, from this viewpoint, a **supra-** or **metasystem**.

Conversely, any part of a system may generally be considered, in turn and at its own **level**, as a whole, within which parts can be identified.

FEIBLEMAN and FRIEND wrote: "**Subparts**, parts and wholes are the three **levels** necessary to constitute an **organization**" (1969, p.49).

Of course, there may be quite more than three **levels**, as shown in **living systems** by J.G. MILLER.

We should try to avoid a false **dichotomy** between parts and wholes. While, according to M. MARUYAMA, "There is no "whole" prior to parts" (1976, p.204), this author presents the "mutualistic view": "... there are only parts, and parts create a *system* of **interaction**" (Ibid).

3780

WHOLISM¹⁾

A near synonym for "**holism**", and even "systemism".

Some few authors use this word because "systems", "systemics", etc... are frequently associated with computer technology or **systems analysis**, or **systems engineering**. Such confusion obscures the deeper meaning of "wholism" as the specific global or wholesale approach to complex systems and/or **issues**.

As to "holism", it has now been kind of "hijacked" by an important group of practitioners of non main-line medicine.

Moreover, it has been sometimes unduly defined as antagonistic to **reductionism**, while of course both **methodologies** should be used in a complementary way, according to need. In fact, the multiplication of denominations for the **systemic approach** is confusing in itself.

3781

WICKED EFFECTS:

→ **Effects (Side)**

3782

WOBBLE²⁾

A unsteady **oscillation** of small **amplitude**.

One of the simplest "**catastrophes**", resulting from the **change** of a punctual **attractor** to a circular one.

3783

WORK FLOW^{1) - 2) - 4)}

A circuit linking successive steps in a complete **process**.

An example is to be found in the **process** of buying some commodity:

- consulting available **information**
- obtaining approval from technical and financial sectors;
- ordering the commodity;
- receiving and approving it;
- transmitting it to the sector in need for it and the corresponding **information** to accountancy.

Such flows are generally repetitive.

Workflows are analogous to **inputs** procurement, inside **transformations** and **outputs** in biological systems.

3784

WORK (Useful)¹⁾

The **activity** a system is able to exert on itself or on its **environment** in order to maintain its **dynamic stability** or to increase its **organization**.

The potential of the system for useful work depends on its already acquired internal **organization** and of the **thermodynamic** of its **equilibrium relation** with its **environment**

3785

WORKSHOP⁴⁾

"A teaching-training seminar which emphasizes free discussion and exchange of ideas along with principles, concepts, practical **methods**, and skills for **problem solving** and/or professional development" (UNEP - UNESCO, 1983, p.31).

In research on complex **situations** or **issues**, workshops are ideally **transdisciplinary** in order to produce a cross-fertilization among participants.

3786

WORLD ENGINE^{1) - 2)}

This striking concept, a forerunner of LOVELOCK's GAIA, was formulated as early as 1924 by A. LOTKA, who thus introduced the first ecological **model** of the planet as a globally connected system, as shown in figure (1956, p. 331).

see figure next page

LOTKA understood moreover that the world engine functions *cyclically*, and is a gigantic dissipator of **energy**. He added: "... in detail the engine is infinitely complex, and the main **cycle** contains within itself a maze of subsidiary **cycles**. And, since the **parts** of the engine are all interrelated, it may happen that the **output** of the great wheel is limited, or at least hampered, by the **performance** of one or more of the wheels within the wheel... If the working substance, or any ingredient of the working substance of any of the subsidiary **transformers**, reaches its **limits**, a **limit** may at the same time be set for the **performance** of the great **transformer** as a whole. Conversely, if any one

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Figure: see entry **WORLD ENGINE**

The World-Engine

From A. LOTKA: 1956, p. 334

of the subsidiary **transformers** develops a new **activity**, either by acquiring new **resources** of working substance, or by accelerating its **rate** of revolution, the **output** of the entire system may be reflexly stimulated" (Ibid).

This is LOTKA's Principle of selection for maximum power **output**, which refers to **eco-systems**, i.e. complex **networks** of **complex systems**.

LOTKA perceived clearly that the world engine undergoes a permanent **evolution** which improves it, through an increase of **complexity**.

The correlations with Prigoginian **thermodynamics** of **systems far away from equilibrium** and with BÉNARD's **dissipative structuration** are obvious.

3787

WORLD GOVERNANCE^{1,4)}

The rapid and complete **integration process** of a **world system** now ongoing introduces the issue of world governance. This is probably the most critical ever **issue** in the **evolution** of mankind.

The existence and possible use of massive destruction weapons implies the possibility of self annihilation of the human species, if not all life on this planet.

World governance is typically a mega-systemic matter

Every aspect of human life in relation to the natural **environment** as well as to the internal **organization** of human **groups** at every conceivable **level** must enter into the global **panorama** of the world governance issue.

The present world **situation** is a confused **network** of muddled **interactions** of multiple different kinds and, obviously, no single individual, nor group could even dream of understanding this **whole** in any detail.

The only basic feature is that multiple and dangerous contradictions are present in every domain we can think of. Only one basic idea seems clear; we (i.e. the six billions inhabitants

of the planet) must harmonize our **symbiosis** with our planetarian **Mitwelt** (**environment**) and eliminate the dangerous and sometimes murderous disfunctionalities, oppositions and misunderstandings that lead everyday to thousands of premature deaths.

Our problem is at first a matter of **understanding** in systemic terms of the conditions that would lead to our demise or **survival**. Secondly, we must find out how we could avoid the first and secure the second. This is also a matter of cybernetic and systemic understanding.

And finally, if not all, at least a considerable majority of people should seek **consensus** through **conversation** and assume their own **responsibility** in practical **action**. The growing number of groups and institutions (governmental or primary) that are reaching **consciousness** of evermore numerous aspects of the global issues shows that we are on our way. But it is a race against time.

In this sense systemic and cybernetic research is much more than an academic topic and could finally become a decisive global life saver. It could provide us with **tools** for understanding and the **education** and **training** of better helmsmen.

→ **Evolutionary learning communities;**
Syntony Quest

3788

WORLD HOMEOSTAT SYSTEM (WHS)¹⁾

"A central **guidance** system operating within the world system and regulating its **functional states**" (E. LASZLO, 1974, p.148).

This is a model of a global **regulator** proposed by E. LASZLO. It reminds of FORRESTER's **World Dynamics**, which is in a sense, an intent to create a **world model**, obviously the first step toward LASZLO's WHS. However, the controversies aroused by the **Club of Rome world models** showed that the proposal is not simple.

LASZLO's idea also reminds of LOVELOCK's **Gaia concept**, wherein the **guidance** is *intrinsic* to the **ecosphere** itself.

3789

WORLD MODELS^{1) - 5)}

Very global models aiming at **forecasts** of planetary long term **trends** in demography, ecology, economy and social evolution.

Around 1970, the **Club of Rome**, using J. FORRESTER's **systems dynamics** in its most general form ("World Dynamics"), started a series of world models, which were heavily criticized for methodological, ideological and socio-political reasons.

Already in 1974, E. LASZLO stated: "Because the world is a highly heterogeneous system, with multiple **hierarchic levels** and a large number of **relevant variables**, constructing a detailed global **structure** is a colossal task" (1974, p.124). So it indeed proved to be.

As to the **methodology**, and in a very general frame, G. KLIR writes: "As a rule, genuine systems problems are computationally extremely difficult. They are often made tractable by overly strong simplifying assumptions that are usually not stated. The resulting **methods** can then deal with sizable systems emerging from practical applications and produce "impressive" results, but the significance of these results is questionable at best" (1993, p.50).

The relative failure of world models somewhat discredited systems views in general and G. KLIR thus adds: "Such methodological dishonesty is contrary to the spirit of **systems science**. The latter is not interested in producing immediately marketable methodological tools at the cost of convenient simplifying assumptions whose validity is dubious, but rather in pursuing basic methodological research involving genuine systems problems" (Ibid).

3790

WORLD ORGANIZATION OF SYSTEMS AND CYBERNETICS (WOSC)¹⁾

This Organization was created in the 1960's by the British cybernetist Prof. J. ROSE. It publishes since 1971 the Journal "Kybernetes". It organizes every three years an International Congress of Systems and Cybernetics.

Prof. St. BEER was President of the WOSC until his untimely disappearance in 2003.

Prof. R. VALLEE (Université Paris-Nord, France) is the General Director of the Organization and maintains its presence in Europe

3791

WORLD (Small)

→ **Small world**

3792

WORLD (Surrogate)

→ Surrogate world

3793

WORLD SYSTEM¹⁾²⁾⁴⁾

A global **model** of the **man-planet system** in the making.

Such a model, which may become an absolutely need for mankind **survival**, does not yet exist.

It should integrate all and every aspect of human existence as related to the planetary **environment** (*Mitwelt, Umwelt*) and to social **organization** in the widest all-embracing sense.

Systemics and Cybernetics appearance between 1948 and 1960 are probably a kind of immunological reaction of mankind confronted with a growing danger of self-annihilation.

The new models of **processes** and ways of organization that thus emerged are doubtless first rate and indispensable **tools** for global **understanding** and- hopefully- satisfactory **management** of the world system model to be elaborated.

As an example- still specific, but already wide-reaching- of such a possible model, the Slovenian work on "**System thinking** and climate change system" (T. ECIMOVIC, M. MULEJ, et al., 2002) is an outstanding effort.

3794

WORLDVIEW

Because of its frequent use by some systemists the German word **Weltanschauung**, equivalent to worldview has been adopted, at least in some cases.

→ **Weltanschauung**

3795

WU-LI, SHI-LI, REN-LI (WSR): an Oriental Approach to Systems¹⁾⁴⁾

The following note is merely a too short summary of a very significant and original development taking place mainly in China.

GU Jifa and ZHU Zhichang write: "Chinese philosophy since the ancient times has been characterised by its belief and intention towards integration, harmony and holism. The three major ancient Chinese philosophical traditions (Buddhism, Taoism, and Confucianism) all emphasize harmony e.g., the unity of TIEN (objective existence), TAO (mechanism of the Universe) and REN (human intention); the unity of YIN (negative, lunar, feminine, soft, etc) and YANG (positive, solar, masculine, hard, etc); the unity of ZHI (knowing) and XING (doing), etc. All of these believe that human beings simultaneously understand and create the world., Therefore the life world of human conception, intention and action, cannot be properly investigated and researched as if separated from their sur-

roundings. The philosophies also suggest that the TAO (moral), ZHI (knowledge), and XING (action) of human beings are systematically related to the conditioning and support of one another, and therefore cannot be "artificially" isolated from one another" (1995, p. 31)

The authors also explain the Chinese medical notion of QI: "...all organic parts and sub-systems in a human body are integrated by QI. QI has no physical form. Nor is it a type of object matter. Yet it has effects like an electronic or magnetic field. It is QI that co-ordinates interactive performances through-out all parts of the human body. Subsequently problems in one part of the body may find their behavioral causes in another part of the body, or in the environment. Compared with their Western counterparts, the Chinese uphold a cultural tradition which focuses more on GUANXI (relationships), which may be between members of a family, within or between organizations, and within society as a whole" (ibid, p. 32)

The authors present WSR in the following terms: "The philosophy underlying the WSR approach suggests that social situations are constituted by WU (objective existence) SHI (mechanisms of the universe), and REN (human intentions).

Therefore any project tackling such situations should consider all WU-LI, SHI-LI, and REN-LI elements in a holistic manner, although a single LI may manifest itself as dominant or a more urgent element than the others of certain stages" (ibid)

In a graphical representation the authors consider:

WU-LI (Objective existence) as the subject of knowing and studying
SHI-LI (Mechanisms of the universe) as being in need of understanding and modelling)
REN-LI (Human relations) as in need of co-ordination and compromise

WSR also presents dynamical aspects that the authors represent in a closed circle:

- understanding desires
- investigating conditions
- formulating objectives
- creating models
- co-ordinating relations
- implementing proposals

...and back to understanding desires.

The similarity with WARFIELD's generic design or FLOOD's and JACKSON's Total Systems Intervention seems obvious.

Finally, the authors state that "the WSR process should not be read as a step-by-step Chinese "cookbook", (but) rather it should be tailored by participants in accordance with their situational requirements" (p. 37) and give examples of the practice of WSR.

For more information, see also PRESSMAN, T.E. (1992)

Y

3796

YIELD¹⁾

The **output** of a system, usable by other systems.

Obviously, as the system depends of its **environment** for its **inputs**, yields are generally variable with environmental conditions. **Variations** may be more or less **cyclical** in an intricate way, depending on the **interrelations** of the system with other ones, which may be its competitors for **inputs**.

Yields in ecological systems have been studied by V. VOLTERRA, A. LOTKA, H.T. ODUM and many others.

In very complex **ecosystems**, not perturbed by man, yields of the different species tend to vary only slightly. According to H.T. ODUM: "If the yield is not taken, the stocks and system **structure** develop" (1983, p.93). Of course, there are **limits** to this development.

ODUM moreover states: "There is an optimum removal **rate** that optimizes the stock to its **energy input** with the maximum steady drain of the yield. This is called the optimum catch" (ibid).

3797

YIELD (Maximum sustainable)^{1) - 4) - 5)}

The concept of maximum sustainable yield is generally **equilibrium-centered**, i.e. based on the postulate that the **population** or system considered merely fluctuates between permanently stable **limits**, which will not be crossed.

However, as stated by C.S. HOLLING: "An **equilibrium-centered** view is essentially static and provides little insight into the **transient behavior** of systems that are not near the **equilibrium**. Natural, undisturbed systems are likely to be continually in a transient **state**; they will be equally so under the influence of man. As man's number and economic demands increase, his use of **resources** shifts **equilibrium states** and moves **populations** away from **equilibria**" (1976, p.73).

No vegetal, animal or human **population** exists isolated from its **environment**, partially made of other species. Thus, some **disturbance** affecting an apparently unrelated system, may well in due **time** propagate itself to the **population** under research. And it could do so in unforeseen ways, triggering wide **divergences** from the former **equilibrium**. It may for example lead the **population** under review to cross an **instability threshold** and, as a result, introduce **bifurcations** and a **chaotic behavior**. This explains why, for instance, overfishing of one species, followed by a **population** crash, may lead to a permanently depleted **population**: the global **equilibrium** has been permanently altered in a way detrimental to the species under focus.

Such **situations** start now to appear in widely different systems under the pressure of massive abuse by man.

Z

3798

ZEITGEIST¹⁾⁴⁾

"The dominant set of **concepts**, opinion and prejudices proper to some **culture** during a historical **period**"

The meaning of this german word is "the Spirit of the time"

An example would be the set of Victorian values and their practical translation in everyday life.

The concept was developed by HEGEL in the 19th Century, along with the concept of "**Weltanschauung**".

3799

ZERO GROWTH^{1) - 2) - 4)}

An hypothesis purporting the possibility for **human systems** to reach a **steady state**, or **dynamic stability** after a **period** of **exponential** or **logistic growth**.

Such hypotesis can be applied to **populations**, industrial sectors, economic **development**, or **human ecosystems**. It was very widespread, and controverted, during the seventies.

The general conditions of systems **growth** seem to support the hypothesis. However, a **steady state** could be reached after very different **growth** curves, from a smooth **logistic asymptote** to dramatic crashes after more or less considerable **overshoot** resulting from exponential growth.

Moreover, there is a wide variety of **human systems** at different stages of **growth** and their evolution is not synchronized. As a result, rivalries do appear and become a source of economic, political and even ideological struggle, which completely obscures the **issue**, specially in absence of any **systemic understanding**.

3800

ZERO POINT²⁾

The place where, or moment when a system is in a neutral **state**.

This point corresponds to the **situation** in which the system obtains no advantage, nor suffers any adverse effect.

3801

ZERO-CROSSING²⁾⁵⁾

"The place where the value of a **function** passes from positive to negative, or vice versa" (M. BODEN, 1988, p.60)

3802

ZERO-SYSTEM^{1) - 2)}

"A system of **components** that has not developed **functions** yet" (V. CSANYI, 1993, p.263).

CSANYI develops as follows this very important and not yet widely known concept, which gives a clearer understanding of **autogenesis**:

"A zero-system has no **organization**. A precondition for starting a **self-organizing process** in a zero-system is the presence of a minimal **set of components** which is able to replicate and which fulfills the following **criteria**:

"1. It contains at least one **cycle of component-producing processes**;

"2. At least one of the **components** participating in this **cycle** can be excited by the **energy flux** flowing through the system" (Ibid).

CSANYI calls such minimal sets of **components** "**autogenetic system precursors**" (AGSP)".

3803

ZEUGMA¹⁾⁵⁾

A greek word whose **meaning** is **link**, **connection**. It has been introduced by the Greek psychiatrist and systemist N. PARITSIS in his study of **psychological contexts**. (2000)

3804

ZIPF LAW^{1) - 2)}

A numeric **correlation** between the **frequency** of occurrence of different words in a **language**.

Zipf showed that the most common word ("the" in English) occurs 10 times more than the 10th more common word, 100 times more often than the 100th most common word, and so forth.

This intriguing feature seems to be a quite general property, probably correlated to **fractals** and **renormalization** properties.

Recently, some genetists found that non-coding DNA (so called "junk" DNA) follows the ZIPF relation, i.e. has the **structure** of a **language** (Ph. YAM, Scientific American. vol 272, 3, 1995)

Zipf Law is obviously a **power law**, as it applies to the same general type of **phenomena**, for instance in the use of words in a **language**, or in the number of cities as ranked by their **population**. It reflects a collective property emerging from a statistical **behavior** or **relation** among numerous **elements** of similar individual characteristics within a **class** or a **region**.

3805

ZONE of ACTIVITY^{1) - 4)}

Part of the **environment** where a system is capable to exert some **action** (A. LOTKA, 1956, p.344-5).

This concept, can be applied to all living and meta-living **systems**, if one understands by **action** the product of a **correlation** device between the system and its **environment**.

For some physical systems, as for example planetary systems or stellar ones, the **correlation** exists and also defines a zone of activity. However, this zone is a **field**, more or less diffuse and it could be spoken of **receptors**, **elaborators** and **effectors** without semantic misuse.

LOTKA emits some interesting comments:

1. The systems **behavior** can be deeply modified and eventually polarized if a new **element** or factor is introduced in its zone of activity;
2. The dimensions of this zone may be modified if the system increases or reduces somehow its **perception** or action's ability;
3. There is an important difference, within the zone of activity between merely reactive **behaviors** and duly planned ones;
4. The zones of activity of two or more interactive systems are not necessarily symmetrical, nor fully superposed.

LOTKA distinguishes a "zone of influence" and a "zone of mobility". The second one does not necessarily includes the whole of the former one. LOTKA gives the interesting example of the constellations used by a seafarer to orient himself, but on which he has no power whatsoever. Or, in human societies, the influences that an individual receives are *generally* quite more important than those he is himself capable to exert.

3806

ZOOIDS¹⁾²⁾⁴⁾

The small individual **organisms** that compose **colonial** ones.

Some examples are the amoebae that constitute the collective form of the slime mould **Dictyostelium discoideum**; or the thousands of small animals that compose the Portuguese man-of-war (Physalia).

It is in fact their **integration** in a functional individual on a higher **level** of **complexity** at which they interact in new emerging specific ways which differentiate the zooids from similar **elements** in a more **autonomous** condition.

The extensive use of the term has been sometimes criticized. However, each **organism** is in fact a collectivity, whether of **cells**, or of more complex individuals, as in a beehive or a **swarm** of ants...or human societies.

At the **living systems level**, zooids are similar to particles in atoms, atoms in simple or more complex molecules and organic molecules as living matter **components**.

3807

ZOOSEMIOTICS¹⁾⁴⁾⁵⁾

The study of **signs** in the **communication** between animals (T.A. SEBEOK, 1972)

This study has been since that time abundantly fertilized by studies in animal psychology in the field and in laboratory (J. GOODALL, FR.DE WAAL, etc.)

APPENDIX

BIBLIOGRAPHY

A complete bibliography of Cybernetics and Systems would be a considerable work in itself. The following list should be considered merely as a partial one. It is moreover centered on the literature that has been used in this Encyclopedia. In any case, it is believed that no basic works have been ignored.

The bibliography contains a significative number of references in languages other than English (Dutch, French, German, Italian, Spanish, and others), which will be useful for researchers in some countries without any easy access to literature in English.

Many of the items enumerated have been directly used in the Encyclopedia as indicated under the respective entries.

Nearly all the others have at least influenced on the work.

The following basic collections should be widely consulted for wider reference.

Journals

* Sponsored by the International Federation for Systems Research (Secr. Gehrard CHROUST, Univ. of Linz, Austria, who also publish a quarterly Newsletter of the IFSR)

(): number of issues per year

Analyse de Systèmes(4), published since 1974 under the direction of J. P. ALGOUD in Paris by the Groupe International de Formation et de Recherche en Théorie et Analyse de Systèmes

Behavioral Science (4)*, published since 1955 under the editorship of James G. MILLER in San Diego, CA, U.S.A. (discontinued end 1996, fused with Systems Research)

CASYS, published since 1998, edited by Institute of Mathematics, Univ. of Liège, Belgium, ed. Prof. Daniel DUBOIS

Cybernetica (4), published by the International Association of Cybernetics, Namur (Belgium), since 1956 (discontinued end 1998)

Cybernetics and Human Knowing (4), published since 1994 by Sören BRIER, Aalborg, Denmark

Cybernetics and Systems (6)*, since 1970, now edited by Robert TRAPPL, Austrian Society for Cybernetic Studies and published by Taylor and Francis, Bristol, Pennsylvania, U.S.A.

Human Systems Management (4), since 1981, under the editorship of Milan ZELENY, Fordham Univ. at Lincoln Center, New York.

International Journal of General Systems (4)*, since 1974, edited by George KLIR and published by Gordon & Breach

International Journal of Systems Science (12): since 1970. Current editors are J.C. HARRIS and Hugh DURRANT WHYTE of United Kingdom. The publisher is Taylor and Francis.

Journal of Cybernetics, published from 1970 on by the American Society for Cybernetics (Probably discontinued. Present status unknown)

Kybernetes (4), published by the World Organization for Systems and Cybernetics since 1972, whose editor is now Robert VALLÉE, currently in charge of the WOSC

Kybernetik, published in Germany during the 70's (present status unknown)

Newsletter Cybernetics Academy Odobleja (Ir), since 1983 in Milano, Italy (present status unknown)

Revista Internacional de Sistemas (4), since 1989 by the Sociedad Española de Sistemas Generales, under editorship of Rafael RODRIGUEZ DELGADO († 1997)

Revue Internationale de Systémique (4), since 1986, now under editorship of Bernard PAULRE, published by Dunod and Gauthier Villars, Paris, France (discontinued end 1998, substituted by www.res-systemica.org)

Sistemica (Ir), published since 1990, under the editorship of Ricardo RODRIGUEZ ULLOA, by Instituto Andino de Sistemas, Lima, Peru

Systemica (Ir.), since 1980, under the editorship of Gerard de ZEEUW et al., published by the Systeem Groep Nederland, Delft Univ. Press, Holland

Systemist (4), since 1978, under the editorship of Frank STOWELL, by the United Kingdom Systems Society, Nuffield Center, Portsmouth, U.K.

Systems Practice (6)*, since 1987, under the editorship of Robert FLOOD, published by Plenum Press, New York and London (discontinued end 1997, fused with Action Research)

Systems Practice and Action Research (6) published since 1998 by Kluwer-Plenum Press, editor Robert L. FLOOD

Systems Research (4)*, since 1984, now under editorship of Michael C. JACKSON, published by J. WILEY, New York and London.

Some few other journals on Systems and Cybernetics in general have appeared... and disappeared from 1955 on. It has not been possible to trace them recently.

A number of journals about Biocybernetics, Control systems, Fuzzy sets, Management and other more specialized fields do exist and have been occasionally mentioned in the bibliography.

"Behavioral Science" and "Systems Research" have been merged in 1997. The publisher is Wiley. (discontinued end 1996, fused with Behavioral Science)

Systems Research and Behavioral Science (6), published since 1997 by J. Wiley, editor Michael C. JACKSON

Proceedings

A considerable number of Proceedings of international and national meetings have been published since 1956 on.

They are unfortunately quite out of reach for anybody. In some cases they may even have disappeared. This is a pity, because these proceedings are an exceptional source of interesting - and even at times outstanding - material that cannot be found anywhere else.

The following have been consulted:

-IDIMT. Interdisciplinary Information Management Talks. These Proceedings of an Annual Meeting in Praga (Czech Republic, since 1998) are published by Universitätsverlag R. Trauner, Linz; 11 vols. published until 2003

- Proceedings of the Annual Meetings of the ISSS (formerly SGSR and ISSR): 40 meetings to date (probably more than 30.000 pages altogether!)

- **Proceedings of the bi-annual meetings of the Austrian Society for Cybernetic Studies**, Vienna, Austria (13 meetings to date, since 1972)

- **Proceedings of the tri-annual Congresses of the International Association of Cybernetics**, Namur, Belgium (Since 1956: 14 Congresses to date)

- **Proceedings of the European Congresses on Systems Science** (two Congresses since 1989)

- **Proceedings of some of the Baden Baden meetings** organized every two years by G. Lasker of Univ. of Windsor, Ontario Canada

The International Society for Systems Science published from 1956 until 1984, an excellent Yearbook, which unfortunately seems to have been discontinued. This collection was also widely consulted.

Occasional papers on Systems and Cybernetics have appeared in many other journals since 1952 and have been also quoted as widely as possible.

ABMA, T.(ed.): "Telling tales: on evolution and narratives"- JAY Press, Stanford, CT, 1999

About the Author

Charles François is a Belgian citizen, born 1922 and retired from the Belgian Foreign Service since 1987. He was educated in Belgium and lived in Central Africa from 1945 to 1960, first as an administrative officer and later on as owner of his own business. His first contact with Cybernetics was in 1952 through Wiener's foundational 1948 work on Cybernetics.

In 1958 he became a member of the former Society for General Systems Research (Now ISSS). Participant from 1970 on in numerous Meetings of various Systems and Cybernetics Societies, he is also member of the board of some of them, and integrates the editorial board of various journals on Systems and Cybernetics. Author of numerous papers on systemic topics, he also published in French a book on: «Cybernétique et Prospective» (International Association of Cybernetics, Namur, 1976) and an «Introducción a la Prospectiva» in Spanish (Pleamar, Buenos Aires, 1978). In 1985 he published in Spanish his study on «El uso de Modelos Sistémicos-Cibernéticos como metodología científica (Systemic-Cybernetic Models used as scientific methodology) and in 1986 «Enfoques Sistémicos en el Estudio de las Sociedades» (Systemic Approaches to the Study of Societies).

In 1992, he published his «Diccionario de Teoría General de Sistemas y Cibernética» (GESI, Buenos Aires), **the first work of its kind in Spanish** (475 terms). In 1997 his International Encyclopedia of Systems and Cybernetics was edited by K.G. Saur, München.

François lives in Argentina since 1963 and created GESI, the Argentine National Division of the ISSS in 1976, being presently its Honorary President.
